Some embedded controllers use a simplified version of BASIC. BASIC was invented before personal computers but then initially became the main language of personal computer programming. Microsoft still sells its Visual BASIC software for program development. BASIC is a very simple higher-level language that is easy to learn and use. The program created is then translated into binary code by a compiler. Alternately, the microcontroller runs a program called an *interpreter* that resides in memory and executes the program, a command at a time.

The following program is written in PBASIC, a simple version of BASIC used with an embedded controller called the BASIC Stamp made by Parallax. It uses a PIC microprocessor and stores a program in flash memory. The program causes an LED to flash off and on.

```
Do
    High 7
    Pause 500
    Low 7
    Pause 500
Loop
```

The first line tells the controller to make the output pin 7 on the microcontroller high or binary 1. The next command says pause for 500 ms or one half second. Next, pin 7 is made to go low or to binary 0 via the Low command. Pause makes it stay there for another 500 ms. Finally, the Loop command causes the program to loop back and repeat itself again and again. This is what is called a Do…Loop for repeating a program over and over again. The result is an LED that turns off and on at a 1000-ms (1-s) rate.

C Language

The C language is referred to as a higher-level language in that the various syntax and terminology of the language usually translates into multiple binary machine instructions. The C language lets you write the program in a more conversational or casual format using English instead of cryptic mnemonics and other terms. The language is a bit of a challenge to learn, but after that programming goes much faster. A compiler converts the C language program code into binary code.

A simple C program may appear like this:

```
#include <stdio.h>
#include “stdio_setup.h”

int main (void)
{
UartInit();
int x, y, z;
x = 38;
y = 57;
z = y – x;
printf(“The difference is %d”, z);
}
```

The #include statements tell the compiler to include instructions to accomplish some of the actions specified by the program. The int main(void) is something that must be included in all C programs. The UartInit() tells the compiler to set up an output port for the result of the program. An open bracket symbol indicates the beginning of the program. The next line identifies three integer values x, y, and z; 38 is assigned to x, and 57 to y. Then the difference between the two is designated z. Finally, the printf line accesses a subroutine that causes the expression “The difference to be printed is 19.” The z value is substituted for %d indicator. Note that all lines of the program end with a semicolon. The end of the program is indicated by the close bracket.

PROGRAMMING

Programming is the process of solving a problem with a computer. Sometimes called coding, programming is a multistep process that involves identifying and defining the problem, developing a solution to it, and then preparing a sequence of instructions that solve the problem.

There are five steps in the programming process. These are as follows:

1. Problem definition
2. Solution development
3. Program coding
4. Program testing and debugging
5. Documentation

In problem definition, you state as clearly as possible what you want to accomplish. Typically it is best to make a written statement of the problem. By actually writing out what is to be accomplished, you will think through the problem more thoroughly. Making charts, tables, graphs, drawings, or the like is also useful. Define your inputs, define the desired outputs, and then outline the processing steps required. Thorough problem definition produces a solution faster and easier. This is the most important step in programming.

Once the problem has been defined, you are ready to develop a solution. It is virtually impossible to give you guidelines on how to do this. Developing the solution is really the creative part of programming. The best way to learn it is by actually doing some programming. The more problems you solve, the more creative and proficient you will become. In any case, developing the solution is best done when the problem has been clearly defined and when you have a good working knowledge of the MCU, its instruction set, and the programming language you are going to use.

The solution you develop is typically a step-by-step procedure. Each step in the solution will cause some part of the problem to be solved. A step-by-step sequence of procedures for solving a specific problem is called an *algorithm*. An algorithm may be a mathematical formula or just a recipe-like list of steps.

A useful tool in developing a solution to your programming problem and in preparing your algorithm is the *flowchart*. A flowchart is widely used by programmers to provide a visual or graphical presentation of the solution. Sometimes the solution is more easily seen or understood by blocking out a problem in graphical or visual form.

Flowcharts are made up of a number of simple symbols that depict typical computer operations. Fig. 13.1 shows the most commonly used symbols. The two most important symbols are the rectangle and the diamond. The rectangle simply specifies some particular operation. The diamond is a decision block. It usually asks a question that can be answered with a yes/no or true/false decision. This is the way most computers "think" or make decisions.

DECISION BLOCK
QUESTION OR DECISION ?
NO/FALSE
YES/TRUE

FIGURE 13.1 Flowchart symbols.

An example of a flowchart is given in Fig. 13.2. This flowchart represents the solution to a typical MCU problem. The problem in this example is to determine which of two numbers, A or B, is the larger. The algorithm is to subtract B from A. If the difference is positive, A is obviously greater than B. On the other hand, if the subtraction results in a negative difference, A is less than B, which means B is the larger. The flowchart illustrates the entire problem and solution.

One of the best approaches to programming a solution is to use *structured programming*. Also known as *top-down design*, structured programming is the process of taking the problem and partitioning it into modules that perform the major functions of the solution. In structured programming, you break down a

problem into smaller and smaller logical pieces. Each piece, or module, performs some distinct segment of the solution.

All of the modules are then linked by a hierarchical structure that shows their relationship. This structure looks like an organization chart for a company. An example is given in Fig. 13.3. The main solution is divided up into three major modules. These modules are then divided into submodules that implement the primary module with smaller stand-alone programs. These submodules may then be further subdivided into even smaller logical segments. Some modules may be subroutines that may be used several times or called by any of the other modules or submodules.

Another feature of structured programming is to minimize or, if possible, completely eliminate unconditional branch operations. An *unconditional branch* or *jump* is a command or instruction that changes the order of a program from its normal, logical step-by-step sequence to something that might not be obvious. A common unconditional branch is the GOTO instruction. The tendency is to end one module with a GOTO so that the program branches to a submodule or some other logical segment of code. If too many GOTOs are used, the result is what is normally called spaghetti code. The result is a tangle sequence that is hard to follow in debugging or in maintaining the program.

The benefit of structured programming is that by dividing the program into smaller logical segments, it is easier to code, test, debug, and maintain. Also,

FIGURE 13.3 Structured programming divides a problem into smaller and smaller submodules.

it is easier to work with a smaller program when devising a solution. So if you take the time to do the partitioning up front when designing the program, the actual development time will be shorter, and chances are that the program will work right the first time.

The next step in the programming process is *coding*. This is the process of converting your solution, algorithm, or flowchart into an actual computer program. Here you take the instructions, expressions, or statements of the language you are using and write them in a sequence that implements your algorithm.

A common procedure with many programmers is to first code the solution in pseudocode. *Pseudocode* is a hypothetical or made-up language that is some hybrid of an English language statement of the operation and the actual instruction, statement, or command of the programming language. It enables the programmer to write the sequence of operations on paper first before actually using the language itself. Often the pseudocode can be written from the flowchart. This procedure helps you better see the logic of the procedure before committing to the final program code.

Programming involves much more than just the coding process, which most people associate with the term. Actually, coding usually takes roughly 20% or less of the total time involved in programming. Studies have shown that 40% of a programmer's time is usually devoted to problem definition, structure design, and the development or identification of an algorithm.

Most programmers agree that coding is actually the easiest part of programming. Once you become familiar with the characteristics and syntax of the language of use, and some basic programming tricks, coding becomes fast and easy. The use of subroutines greatly shortens and simplifies the coding process. On the other hand, defining the problem and developing a workable solution is much more difficult.

Once the coding is complete, you will enter the program into the MCU and test it. You enter the program with the editor to create your source code. The computer will then assemble or compile your program into machine code. In either case, the result is the binary object code stored in memory. At this point you are ready for the next programming step, testing and debugging.

Testing involves verifying that your program works. You will want to thoroughly test it to be sure that it does what it is supposed to do. Invariably, most programs do not work properly the first time. You may have made logical errors in sequencing, or perhaps you made errors in entering the code. If you used structured programming, you can test each submodule or subroutine by itself before linking together all of the various modules to perform the total operation.

Whatever the problems are, testing leads to *debugging*. Debugging is the process of working with the computer program and attempting to find errors and glitches. Most languages and program development software have built-in features that facilitate the debugging process. Once all the errors have been found and corrected, the program is ready to use.

The final step in the programming process is called *documentation*. This is an often-neglected but extremely important part of programming. Once the program is written and debugged, it is ready to use. The temptation then is to put the program into use and drop the project. However, it is extremely important that you document the program. Your problem definitions and solution work should be written up and filed away. Any charts, graphs, drawings, flowcharts, and other materials that you developed should be saved. All program listings should also be retained. In fact, it is desirable to prepare a detailed, written statement explaining the algorithm and the procedures involved. This is important for program maintenance, because it may be necessary to change the program at a later date. You may wish to add a feature or correct some part of the program to accommodate new conditions. It is easy to forget what you did months or years earlier. Also the original programmer may no longer be involved with the program. If a new programmer becomes responsible for changing a program, complete documentation is invaluable. Changing a program written by someone else is extremely difficult and, in some cases, virtually impossible without documentation.

The major investment in any programming project is programmer's time. A significant amount of time is usually required to develop a useful piece of software, which is why software is so expensive. In fact, the hardware is the least expensive part of the system in most embedded controllers.

One final word: Some programs may have to be changed over time. As the problem evolves, grows, or changes, the solution will have to be altered to meet current needs. New issues must be faced, or features may need to be improved to save time. In the case of a software product, improvements may have to be made to fix user-discovered bugs, improve performance, or keep the software competitive in the marketplace. It may be necessary to port the software to another MCU or OS.

All of these conditions fall into the category of maintenance. In fact, more time is spent on maintenance than in creating the original software. And, as indicated earlier, the better the documentation the faster and easier the maintenance can be carried out.

Developing Software for Embedded Controllers

The programming process just described applies to any microcomputer, be it a general-purpose personal computer or an embedded microcontroller. However, the procedure is somewhat different if you are developing programs for MCUs that are to be built into other equipment. Fig. 13.4 shows a block diagram of the complete microcontroller software development process.

A typical arrangement is to install the appropriate IDE on a PC. The PC then connects via a USB port to a development or evaluation board containing the target MCU. Next, once you have written your program in the programming language with the text editor, the assembler or compiler is called on to translate

that program into the machine code for the target microprocessor. All this is done on the PC.

Once the program has been written and the machine code generated, you test the program. The personal computer is not capable of executing the microprocessor instruction codes directly. However, an emulator program is usually available in the IDE that will allow the personal computer to test the program. An *emulator program* is a system-level program that duplicates the execution of the MCU instructions on the personal computer. The emulator mimics the microprocessor so that the object code developed under the assembler or compiler can be tested. This allows the programmer to do any initial debugging. The problem with this procedure, however, is that the emulator sometimes does not operate in real time. It will not precisely duplicate the machine-cycle instruction execution rates of the microprocessor. The program will not be executed in exactly the same time frame as with the microprocessor. If time-related functions are important, the program should be thoroughly tested on a prototype of the MCU before being finalized.

Most development software includes a debugger, a program that helps to identify and isolate coding errors, logical errors, and other problems. The next step is to download the program to the MCU. This is usually done by way of a USB cable that connects the PC to the MCU development board or a prototype of the product being developed. Functional testing can then take place. The program is downloaded to the development board and stored in a ROM or flash memory. Thus the microprocessor becomes dedicated to a specific application. Then additional testing can be performed. The program in a ROM is typically referred to as *firmware*, that is, software that exists in an electronic component.

Microcontroller Unit Interfacing

In addition to programming an MCU for a specific task, you also need to interface the MCU to the external devices that make up the device you are designing. Such peripherals are sensors such as light or temperature sensors or controlled devices such as LEDs, relays, or motors. Usually some form of circuit or device is needed between the MCU input/output lines and the peripheral devices.

Outputs. The I/O lines of the MCU input or output standard binary voltage levels. These are typically in the 1.8–5V range for a binary 1 and 0 to a few tenths of a volt for a binary 0. Depending on the MCU and supply voltage, the output lines can usually sink or source current in the 15–40mA range. As a result, the output line can operate low-power devices such as LEDs directly

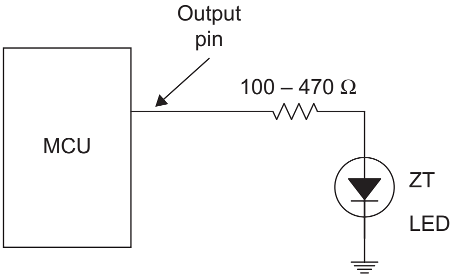

FIGURE 13.5 Driving an LED directly from the MCU output.

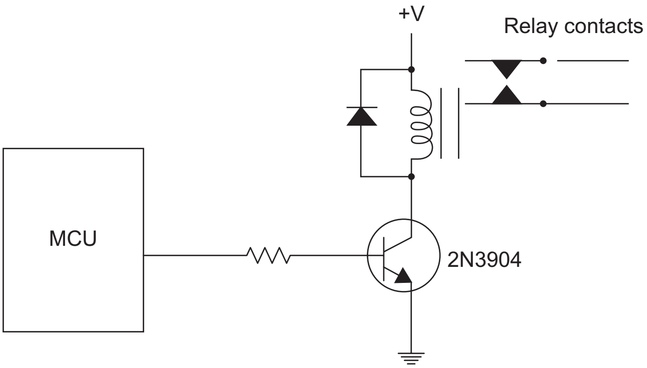

FIGURE 13.6 An NPN driver transistor for higher loads.

without an interface. Fig. 13.5 is a simple example. The resistor limits and sets the current level.

For higher current/voltage devices an interface transistor is usually needed. Fig. 13.6 shows an NPN transistor driving a relay coil. The coil may be operated by the same power supply as the MCU or a higher voltage. The diode protects the transistor from the inductive spike caused by the inductive coil being deenergized. This simple interface can also control a solenoid.

Fig. 13.7 shows a MOSFET operating a motor. A protective diode is usually built into the transistor. If bidirectional control of the motor is needed, the H-bridge circuit discussed in Chapter 12 (Figure 12.20) can be used.

A useful output is pulse width modulation (PWM). A PWM output from an MCU is a continuous DC rectangular wave whose duty cycle can be varied by the program. Some devices or circuits take this signal and average it into a continuous DC voltage. Varying the duty cycle causes the DC average to vary. (See Duty Cycle and PWM and Figure 4.22 in Chapter 4). The duty cycle is selected in the program usually by setting a numerical value. The duty cycle can also be changed by the program. Two example applications are varying the brightness of an LED and controlling the speed of a DC motor.

Inputs. A common input is a switch or pushbutton. The idea is to connect the switch into a circuit that generates a binary 0 or 1. A typical circuit is shown in Fig. 13.8A. The single-pole single-throw (SPST) switch is normally open. The pull-up resistor keeps the MCU input at +5 V. When the button is pressed, the switch contacts close grounding the resistor and producing a zero input. Instructions in the program read the status of the input line. Some action is initiated if the input goes low.

An alternate arrangement is shown in Fig. 13.8B. The resistor keeps the MCU input low or ground and binary 0 level. When the pushbutton is depressed, +5 V is applied to the input. Again the MCU tests the input with an instruction to see if it is binary 1. If it is, some other action will occur.

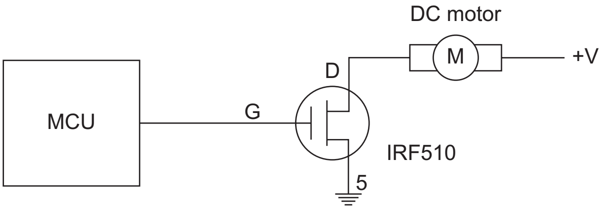

FIGURE 13.7 An N-channel enhancement mode MOSFET driving a DC motor.

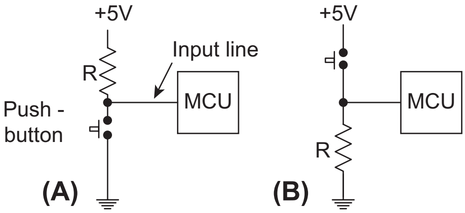

FIGURE 13.8 Using a pushbutton switch to generate an input logic level.

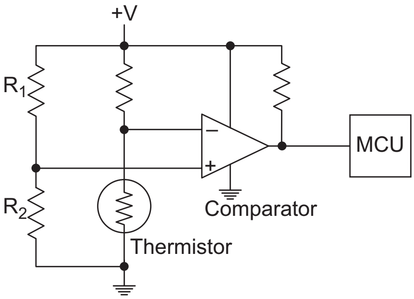

FIGURE 13.9 A comparator and thermistor used for temperature sensing.

A comparator can also be used for an interface. Fig. 13.9 shows a thermistor temperature sensor as the input to the comparator. Voltage divider R_1-R_2 sets the temperature level. As the temperature increases, the thermistor resistance decreases when the voltage from the thermistor divider changes the comparator input and switching the output from a 0 to 1 or vice versa. This signal is applied to an MCU input that is read by the program to determine if the temperature is above or below the level set by the pot. Other resistive sensors such as a photoresistive light sensor can be used for a similar function.

Some devices may require the use of an analog-to-digital converter (ADC). Some sensors or sensor circuits such as a voltage divider or bridge output a DC voltage proportional to the analog quantity being sensed. The ADC translates this voltage into an equivalent binary value that is sent to the

MCU. As it turns out, most MCUs have one or more internal ADCs so no interfacing is needed other than conditioning the analog signal for application to the MCU input.

PLATFORMS FOR LEARNING PROGRAMMING

The best way to learn programming is to start doing it. You will probably need to read some books, participate in online tutorials, or take a formal course. Whatever your approach to teach yourself programming, you will need a platform for learning. The platform, for lack of a better term, is a mix of hardware and software that is organized for learning. Many of these platforms are available for different languages and MCUs. I have reviewed several of these, and described here are the four that I can recommend. They teach either BASIC or C. For complete beginners I recommend those teaching BASIC. If you plan to use C in your work or just want to challenge yourself, select a C platform.

Parallax BASIC Stamp 2

The BASIC Stamp 2 is a complete microcontroller module that uses a Microchip Technology PIC MCU with RAM and flash memory on-chip in addition to inputs and outputs including a USB port for connecting to a PC for programming. It is designed to be built into other equipment or projects. The Stamp 2 is programmed in the PBASIC language. The Parallax Stamp has been around for about 17 years, so it is highly developed and widely used in education to teach programming.

The Stamp 2 is available in a wide range of forms from simple plug-in modules to complete learning kits that include a breadboarding socket, multiple components, and comprehensive project manuals. A free IDE is available for download from the Parallax site. I reviewed the BASIC Stamp Activity Kit that comes with the breadboard and parts. See Fig. 13.10. The manual is a self-teaching guide that instructs you in the BASIC language and electronic interfacing. The kit is a complete package of all the things you need to start learning programming. I recommend it.

PICAXE

PICAXE is another platform that uses a Microchip Technology PIC MCU and is programmed in BASIC. The package is essentially a version of the PIC MCU family in a DIP IC that can be plugged into a breadboarding socket. It has been preprogrammed with firmware that allows the MCU to be programmed by way of IDE software on a PC. Connection is by way of a USB port on the PC. You can then add other interfaces such as sensors or controlled devices as your project dictates. The BASIC language is easy to learn and use. The IDE is a

free download, and there is plenty of support, help, and instruction on the companion website. This is a low cost way to build projects with a microcontroller.

Arduino

The Arduino is a wildly popular microcontroller module that uses an Atmel (now part of Microchip Technology) MCU. The module provides a USB port for connection to a host PC for programming and access to multiple input and output lines. It is programmed in a version of the C language. A free IDE is available for download.

The Arduino has been around for several years now, and multiple versions are available. Dozens of different products are offered by multiple companies. You choose the MCU type depending on your need for memory sizes, interfaces, and I/O ports. My recommendation is to select the simplest form called the Arduino Uno R3. It uses an 8-bit MCU called the Atmel ATmega328P. The Uno is powered by the USB port or an external 5V supply. A free online IDE is available. Using the C language variant provided, you write code to develop a program called a "sketch."

The C language is more daunting to learn than BASIC, but it offers far more power and capability than BASIC. If you want to create more complex projects as a maker or begin to use C in your career, then C is the better choice. The Arduino is probably the best learning platform as there is a large quantity of information available to help you including books, tutorials, and products. One popular type of accessory is the "shield," a small PCB that plugs into the connectors on the Arduino board. The shields are various forms of interfaces and I/O devices such as wireless, motor control, GPS, and many others.

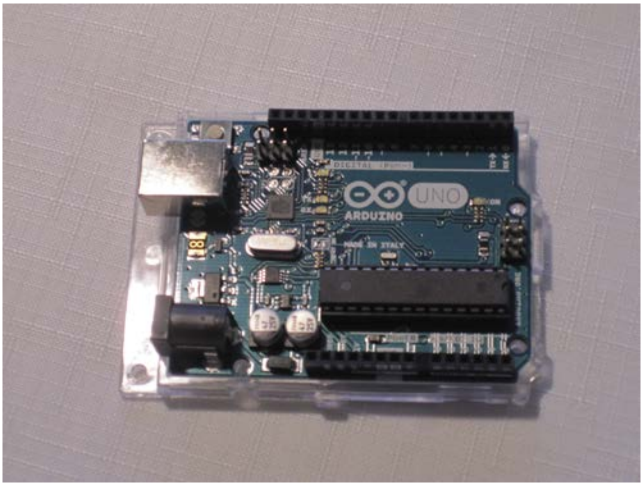

FIGURE 13.11 The Arduino Uno R3 is one of the most widely used microcontroller learning platforms.

I evaluated the Arduino by using supplier SparkFun's Inventors's Kit. See Fig. 13.11. It contains the Uno, a breadboarding socket and a batch of parts to use in interfacing and building external circuits. An instruction manual leads you through projects that demonstrate interfacing and C coding, a good choice for the beginning programmer.

LaunchPad

The LaunchPad is one of the Texas Instruments' development kits for the MPS430 series of MCUs. It comes as a PCB module with the MPS430FR6989 16-bit MCU that features 128 KB of FRAM. Refer to Fig. 13.12. The board also includes some LEDs, pushbuttons, an LCD readout, and other components to use in demonstration projects. A USB port connects the LaunchPad to the PC. Free IDEs are available for download. This is a very serious professional platform for those committed to learning C. No companion instructions are provided but many manuals and tutorials are available online. I acquired the LaunchPad as part of an online college course from Udemy that teaches C with lab projects.

Advanced Alternatives

If you are really adventuresome, you may want to select a more advanced platform. One of the most popular is the Raspberry Pi 2 or the newer more powerful Raspberry Pi 3. Both use a version of the popular ARM type processor, a powerful 32-bit microprocessor. It comes in the form of a development board with memory, I/O, and other resources. The Raspberry Pi uses variations of the Linux OS. IDEs

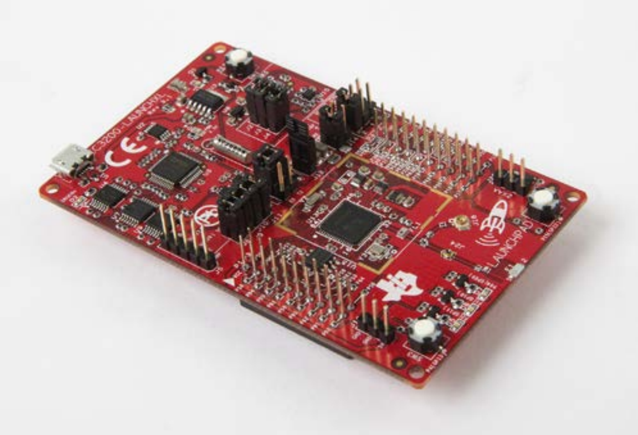

FIGURE 13.12 The Texas Instruments' LaunchPad development board uses an MPS430 microcontroller.

supporting different programming languages are available. Prices are very reasonable. I do not recommend these for beginners, but they can be the next step up after you have mastered programming.

Another interesting advanced option is Parallax's Propeller. This platform uses Parallax's own MCU chip called the P8X32A. It features eight (yes, eight) MPU cores along with memory and I/O. You program it in C, assembler, or a companion language called Spin. Once you have mastered BASIC on your Stamp platform and need more compute power, this may be a good next step for you.

LEARNING PROGRAMMING

There is not enough space in this book to teach a programming language. But you can learn it on your own. If you are not sure about self-learning, you could find a local college or university that offers continuing education courses for adults. Otherwise, give the self-learning idea a try. Here are some suggestions.

Books

There are literally dozens of books covering C programming. Not so many on BASIC. Some books are more specific to teaching the Arduino version of C. I reviewed several, but I can recommend two that may be helpful to you.

- *C Programming With Arduino*, by Warwick A. Smith, Elektor, 2016.
- *Arduino for Dummies,* by John Nussey, John Wiley & Sons, 2013.

I suggest that you go to your bookstore and see what is on hand. Your local library may have some. Alternately, do an Internet search on the Amazon and Barnes & Noble websites to see what is available. I recommend that you invest in at least two or three books as when one is not clear and helpful the others may be.

Learn by Example

Most of the books provide example programs. Kits such as the SparkFun (Arduino) Inventor's Kit and the Parallax BASIC Stamp Activity Kit provide hands-on experiments and projects with typical programs. Initially no programming is necessary. You simply enter the programs and run them. By implementing enough of the programs and analyzing them in detail, you can learn how to program on your own. In fact, with enough examples, you can put together several programs and modify them to fit your needs. If you are just learning programming, I highly recommend one of the experimenter's kits as a great starting point.

Online Tutorials

If you do an Internet search for programming tutorials, you will be surprised at how many there are for both BASIC and C. Some are free and others have a fee associated with them. Some are video based (such as YouTube), others are PDF documents, and some have presentations. Take your pick. Take one to start and then do another just to firm up your knowledge.

Online College Courses

Many colleges and universities now offer online college-level courses in a wide range of subjects. Such programs are referred to a Massive Open Online Courses or MOOCs. Programming is one popular topic. Many are free and others have small fees. If you are interested in a more formal course at the college level, from major institutions, take a look. Go to the websites of Coursera, edX, and Udemy, and search for a C or BASIC course. I selected a course called *Microcontrollers and the C Programming Language* from Udemy. It is taught online by Professor Mark Budnik of Valparaiso University in Indiana. It includes lab programming and interfacing projects using the Texas Instruments' LaunchPad described earlier. The course was offered at very low cost, but the LanuchPad was a minor added expense. A very challenging and time-consuming course but it does the job. There are others you can identify online.

Apply What You Learn

Reading relevant books and taking courses are good ways to get started, but they will not make you a programmer. To learn programming, you must do programming. You must write code, screw up, and retry. You must test the process yourself, failing along the way, and adjusting. This is still the best way to learn programming. Start with small programs and then progress to more complex applications as you improve your knowledge and skill. The projects outlined next will get you started.

Project 13.1

Select a Learning Platform and Language

If you have not already done so, choose your language and acquire one of the platforms or its equivalent described earlier. The complete kits cost a bit more but will get you started faster and easier than just investing in a development board. See Appendix B for sources. You should be able to get started for about $100. It is a good investment.

An interesting exercise is to investigate the programming languages to find out which ones are the most widely used. As a challenge in this project, perform an Internet search to discover the top three most popular programming languages.

A Word About the Following Projects

The projects that follow are intended as demonstrations that show what is possible and how to do it. If you invest in a microcontroller, you can try out these projects. You can just copy the programs into the IDE editor and test them out. The programs are instructive in showing you the programming process. However, you will need further learning before you become a programmer. Your goal should be further study as outlined earlier. Practice makes you more knowledgeable as you try, fail, and then try again and succeed.

Project 13.2

Blink an LED

One of the simplest applications is to flash an LED off and on. You first connect a resistor and LED to one of the output pins on your development board as shown in Fig. 13.5. Some boards such as the Arduino Uno R3 and the TI LaunchPad have this LED already connected on the PCB. As for the code, it is simple. Earlier in this chapter you saw the BASIC code to do this. Here is the code for the BASIC Stamp 2. Wire the LED as shown in Fig. 13.5 using a 470-Ω resistor on pin 7.

```
' {$STAMP BS2}
' {$PBASIC 2.5}
DO
     HIGH 7
     PAUSE 500
     LOW 7
     PAUSE 500
LOOP
```

The first two lines of code that begin with an apostrophe set up the programming software in the Stamp IDE. The remaining code flashes the LED as explained earlier in the chapter.

Project 13.2—cont'd

Below is a listing for the C code to flash the LED. Wire the LED as in Fig. 13.5 to pin 9. Use a 470-Ω resistor. If you are using the Arduino Uno, you can use the onboard LED already connected to output pin 13. Just substitute 13 for 9 in the code below.

```
int ledPin = 9;
void setup()   {
pinMode(ledPin, OUTPUT); }
void loop()   {
        digitalwrite(ledPin, HIGH);
        delay(500);
        digitalwrite(ledPin, LOW);
        delay(500);
}
```

The first line tells the Arduino to assign the variable ledPin to the integer value of 9. The LED and resistor would be connected to pin 9. Next the void setup() command tells the processor to execute the code between the two following curly brackets. The pinMode command tells the processor that pin 9 is an output port. Now the void loop() tells the processor to set up a loop to run the code between the following curly brackets. The digitalwrite command tells the processor to set pin 9 to the high or binary 1 state turning on the LED. The delay command then causes a pause of 500 ms or one half second. Next the digitalwrite command tells the processor to set pin 9 to low or binary 0 turning off the LED. Another delay or pause of 500 ms occurs. Note all command lines have to end in a semicolon. The program then loops back to repeat.

Project 13.3

Use a Pushbutton Switch for Control

This project will illustrate how to apply an input to the microcontroller. The pushbutton is a common input device. The basic interface is like that shown in Fig. 13.8. The micro looks at the input pin and senses the state. If it reads the right condition, it will cause something to happen. In the example to follow, the goal is to flash the LED five times when the pushbutton in depressed. The code in both BASIC and C are outlined below.

Here is the code for BASIC Stamp 2. It uses the same flash code in the previous BASIC example but is modified by to flash five times and then stop. The pushbutton should be wired like that in Fig. 13.8B on pin 5.

```
‘ {$STAMP BS2}
‘ {$PBASIC 2.5}
counter VAR Byte
FOR counter = 1 TO 5
DO
        IF (IN5 = 1) THEN
        HIGH 7
```

Continued

Project 13.3—cont’d

```
        PAUSE 500
        LOW 7
        PAUSE 500
NEXT
LOOP
```

The first two lines beginning with the apostrophe sets up the programming software and must be included. The next line sets up a variable called counter that can be up to a byte long. The DO instruction sets up loop to repeat the program. The IF…THEN line sets up another inside loop that reads input pin 5 to determine its state. It will look at the pin ten times per second. If input pin 5 goes high or 1, it signals the program to execute the code flashing the LED. The program then flashes the LED five times as the loop NEXT command counts the number of flashes and then stops. The LOOP instruction sets up the loop again as the program waits until the button is pressed again. The program is a loop within a loop where the inner loop is conditioned by the number of repeated flashes. The outer loop is conditioned by the state of the pushbutton.

The C code for the Arduino to initiate the five LED flashes is shown below. The pushbutton should be wired as shown in Fig. 13.8A using a 10k-Ω resistor. The code is set up to use pin 2 as the input. Pin 9 is used as an output for the LED as in the previous code.

```
int ledPin = 9;
int inputP = 2;
int val = 0;
void setup()   {
pinMode(ledPin, OUTPUT);
pinMode(inputPin, INPUT);
}
void loop()   {
        val= digitalRead(inputPin);
        if (val == HIGH) {
        digitalwrite(ledPin, LOW);
        } else {for (int i = 0; i < 5; 1++) }
        digitalwrite(ledPin, HIGH);
        delay(500);
        digitalwrite(ledPin, LOW);
        delay(500);
}
```

The program sets up pin 9 as the output for the LED and pin 2 as the input. The void loop() sets up a loop to repeat the flashing five times. The program reads the state of the input pin with the digitalRead statement. If it is HIGH, the button has not been pressed to close the circuit. The “if” statement evaluates the input, and if it is HIGH, it turns off the LED with a digitalwrite command. However, if the input goes LOW, the “else” statement initiates the flash sequence. The “for” statement counts the number or flashes and then terminates the program.

Chapter 14

Soldering

An Essential Skill for Electronics

In this Chapter:

- The importance of soldering.
- What is solder?
- Soldering tools.
- How to solder.
- How to desolder.
- Projects.

INTRODUCTION

Soldering is the process of melting a metal alloy called solder for the purpose of joining together two or more other metals. The solder, when melted, becomes a liquid and flows over the other metals to be joined. When the solder cools, it hardens and adheres to the other metals creating a strong mechanical bond as well as a highly conductive connection. Most interconnections of electronic parts and printed circuit boards (PCBs) are made with solder. For that reason, soldering is an important skill for any electronic engineer, technician, hobbyist, experimenter, maker, or other do-it-yourselfer. This chapter shows fundamentals of soldering and some projects to practice with and learn from.

What is Solder?

Solder is a soft metal alloy made up of tin and lead. The usual mix is 60% tin and 40% lead. Other mixes are available, but the 60/40 category is the most common in electronics work. Solder has a low melting point of about 360–370°F or in the 180–190°C range. It is usually melted with a handheld tool called a soldering iron. The solder is usually made in the form of a thin flexible wire. When melted, the solder becomes a liquid and easily flows over the other metals to be joined. The solder cools and hardens and adheres to the other metals making a solid joint.

Electronics Explained. http://dx.doi.org/10.1016/B978-0-12-811641-8.00014-X
Copyright © 2018 Elsevier Inc. All rights reserved.

Most wire solder contains a continuous core of a material called rosin flux. When heated, the flux melts with the solder and is used as a cleaning agent. The metals to be joined often oxidize and resist the solder. The flux clears away the oxidation and other surface obstacles to allow the solder to adhere to the metals. Some types of solder used in mechanical work use an acid core flux. This is deadly to electronic parts. Never use it. Use rosin core solder only.

Solder containing lead has been ruled undesirable in some applications. Yet it is still the best solder. It will not harm you. You can also get solder without lead. Such solder is mostly tin with a small amount of silver or copper or both. The melting point is typically 5%–10% higher so extreme care should be taken when soldering delicate temperature-sensitive electronic parts.

Soldering Tools

The main tool of soldering is the soldering iron. See Fig. 14.1. It has an insulated handle, a heating element with an AC power line cord and plug. The heating element heats a metal tip that actually does the soldering. The tips come in many sizes but a small tip is best for use on modern components.

Soldering irons are rated by the power they consume and heat they dispense. Ratings run from about 15W to over 100W. For electronics work an iron with a rating of 25–35W is best. It is hot enough to do the soldering but will not do heat damage to sensitive electronic components. Be sure that the soldering iron has a small narrow or pointed tip to accommodate most small electronic component leads.

A helpful accessory is a soldering iron stand or holder to keep the iron from burning the bench or table you are using. Also useful is a wet sponge. It is used

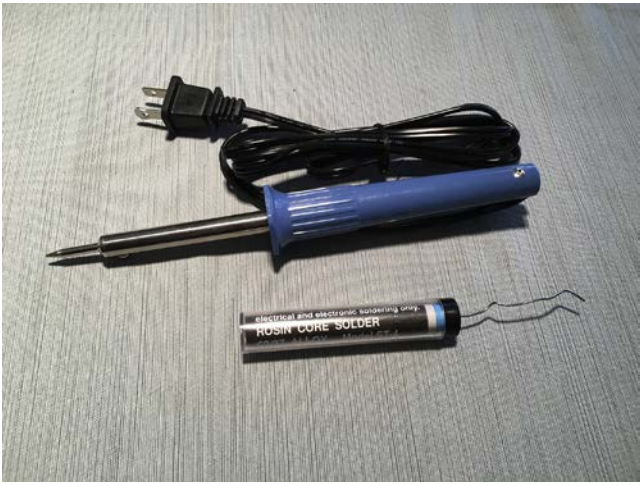

FIGURE 14.1 A common soldering iron used in electronic work.

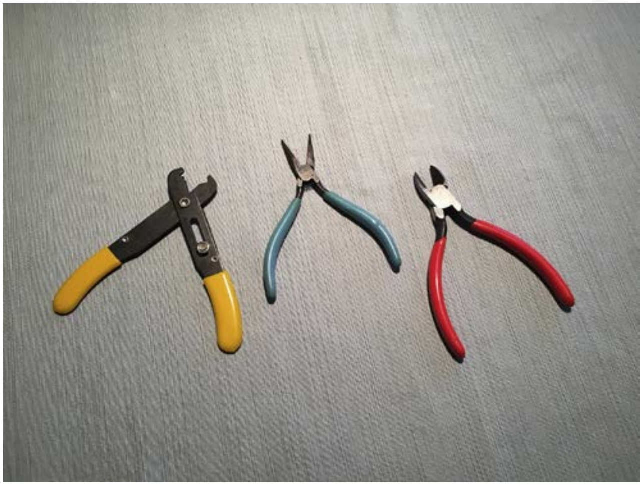

FIGURE 14.2 Tools used in soldering. On the left is a wire stripper. Next is a pair of needle-nose pliers. On the right is a side cutter for wire.

to keep the soldering tip clean. A sponge holder is often part of the soldering stand.

Other useful soldering tools are illustrated in Fig. 14.2. The wire stripper helps remove the insulating cover from wires to be soldered. It cleanly cuts off the insulation without damaging the copper wire. This is a must tool and a mandatory substitution for a knife that can nick the wire while stripping the insulation.

A pair of needle-nose pliers is sometimes helpful in bending or holding component leads or wires. The side cutters are used to cut wires or trim away component leads or wires after soldering. All of these tools speed up and simplify your soldering work and are a good investment.

If you are going to work with tiny surface mount parts, you should have a pair of tweezers to handle them or to hold them in place as you solder. A magnifying glass is also a useful accessory when using tiny parts.

Soldering Procedures

The most common soldering scenarios are soldering wires together or soldering electronic parts to a PCB. Fig. 14.3 shows the first case. When connecting two wires, you first remove any insulation first. You will need an inch or more of bare wire to make the connection. Then make a good physical connection by wrapping one wire around the other as shown. Then touch the clean tip of the iron to the connection. Let the connection heat for a few seconds, then apply the solder. The secret to a good connection is to apply the solder to the heated wires and not to the iron tip. Let the solder flow over the wires until coated. Do not use

FIGURE 14.4 Soldering components to a printed circuit board.

too much solder. Once the solder flows over the wires, remove the iron and let the connection cool. It should look shiny and bright, not dull gray.

Another common soldering situation is connecting components to a PCB. See Fig. 14.4. This shows a resistor lead being soldered to a copper pad on the PCB. The resistor lead is usually inserted into a hole on the board and is then soldered to a copper pad or area on the bottom of the board.

The procedure is to bend the lead and insert it into the hole. The resistor will lay flat on the board as shown. Bend the lead over to hold it in place, then solder. As with soldering wires, or anything for that matter, apply the heat to the copper pad and resistor lead for a few seconds. Then flow the solder over the connection. Do not apply the solder to the iron tip. And do not let the lead or the board move as you solder. Use minimum amount of solder to cover the connection and not more.

Remove the iron and let the connection cool. No movement should occur during the cooling process, or it will produce what is called a "cold" solder joint. Instead of looking bright and shiny the connection will look crumbly and dull gray. Movement during cooling is the most common cause of cold

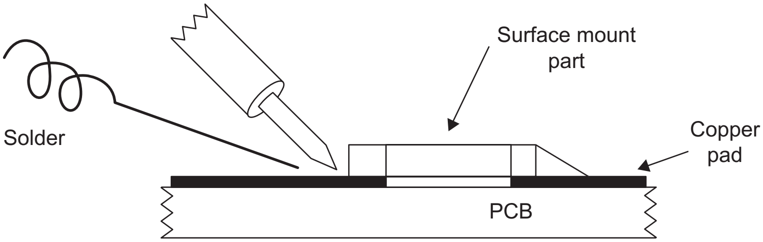

FIGURE 14.5 Soldering a surface mount part to a PCB.

joints. A cold joint does not make a good electrical connection. If this occurs, simply reheat the joint and then let it cool without movement. Do not add more solder.

Fig. 14.5 shows another soldering situation. Here a surface mount part is placed on the top of the PCB and is soldered to a copper pad. No hole is used or needed. Surface-mount parts are tiny and hard to work with. Hold the part carefully in place, then heat the junction of the part and the copper pad. Use a small iron tip to avoid accidentally touching adjacent pads or parts. Then flow the solder over the joint. Use as little solder as possible. Be very careful not to move anything as the solder cools.

There are a couple of precautions to observe. First, use as little heat as possible. Most PCBs are sensitive to heat and with too much heat you can cause the copper pad on the PCB to peel free and possibly break off. This is a serious problem that is often catastrophic for an expensive electronic PCB. Too much heat can sometimes damage a component such as an integrated circuit or resistor. The correct balance is to use just enough heat to melt the solder but not enough to damage anything. A few seconds is all you usually need.

Second, be careful of cold solder joints. Do not move anything as the solder cools. A cold joint will also result with not enough heat. The giveaway is a dull or rough-looking joint rather one that is smooth and shiny. Cold solder joints usually do not create a conductive path between the copper pad and the component. An open circuit is the result.

Third, most connections on a PCB are very close together. Spacings between components and IC pins of 0.1 in. (2.54 mm) or less are common. While you are soldering one connection, be careful not to disturb an adjacent connection. A common problem is using too much solder on a connection that slops over to a nearby connection causing a short or solder "bridge." To fix this, remove any excess solder from the connections to remove the bridge.

Desoldering

A related skill is desoldering. Desoldering is the process of disconnecting things that were previously soldered. It involves removing the solder first, then physically breaking the parts from one another. Desoldering is usually common when

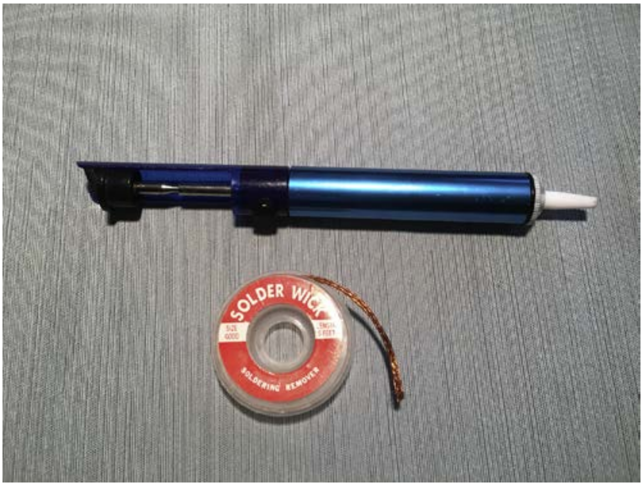

FIGURE 14.6 Tools for desoldering, a solder sucker and solder wick.

repairing electronic equipment by replacing a defective part or when making and correcting a mistake.

The tools of desoldering are shown in Fig. 14.6. The first is a solder sucker. It is a simple vacuum pump that literally sucks the molten solder from a joint. You heat the joint to be disconnected, then simultaneously apply the solder sucker to remove the solder. You usually have to repeat the procedure several times to get the solder off. Once you remove as much solder as possible, you physically pry the parts apart with the tip of a knife or a pair of needle-nose pliers. Be careful not to pull the copper foil pad off the PCB.

An alternative or a companion to the solder sucker is solder braid or wick. This is a narrow flat braid of fine copper wires coated with flux or other chemical that attracts solder. You place the braid on the connection to be desoldered, then heat the braid with the iron. Once the solder melts, it wicks up into the braid. The braid absorbs the solder. As with the solder sucker, you usually have to apply it several times. Be sure to cut off the braid that has absorbed the solder. Always use fresh piece of braid. Again, do not use too much heat and damage the PCB or part.

Projects

The best way to learn soldering is to solder. It is a manual skill that takes a bit of practice. It is not difficult but you do need to try it out first, then practice it several times. The following projects will help.

Project 14.1

Acquire the Tools

If you are planning to do serious electronic work, you need the right tools. The first step is to go get the tools described above. You may be able to get them individually at a DIY store such as Lowe's or Home Depot. RadioShack or Fry's should have them. Online catalog sources, such as All Electronics, Jameco, or others, have them. Some vendors offer complete packages of all the tools in one kit. This complete kit is the best approach if you have no tools now.

Project 14.2

Solder Two Wires

A common need is to connect two wires. An example you may have experienced is the problem of not being able to plug stranded wire into a breadboarding socket. The 9-V battery connector you may have used has stranded wires that are not stiff enough to plug into the breadboard. One way to fix this problem is to attach some short solid hookup wire leads to the battery clip wires. The hookup wires will plug right into the socket.

Here is the procedure:

- Cut two lengths of #22 gauge hookup wire several inches long.
- Use the wire strippers to remove about one half inch (1.25 cm) of insulation from each end of the wires.
- Also strip about one half inch of insulation from each battery clip wire.
- Then wrap the stranded battery clip wire around the solid hookup wire as previously shown in Fig. 14.3.
- Solder the connection by heating the wires first, then flowing solder over them. Do not apply the solder to the soldering iron tip. Also use a minimal amount of solder. Let the connection cool.
- Repeat the procedure for the other battery clip wire.

Project 14.3

Build a Kit

The best way to practice soldering is to build a kit. This was recommended earlier in Project 4.1. If you have not built a kit yet, now is a good time to do so. I recommend the solder practice kit (SP-1A) where you build a siren with flashing LEDs. The kit also provides an area on the PCB to practice soldering skills. You can get this kit from Elenco (www.elenco.com) or Jameco (www.jameco.com).

Any other small low-cost kit such as a power supply will also provide plenty of soldering experience. Refer back to Project 4.1.

Appendix A

Book References

Here is a list of books for those who wish to dig deeper. You will find lots of basic electronics books out there, but these are my favorites as well as some of my own.

American Radio Relay League. *The ARRL Handbook for Radio Communications*; 2017. The focus is on wireless but the book also has excellent coverage of electronic fundamentals.

Ashby D. *Electrical engineering 101*. Newnes/Elsevier; 2008. A good basic book that delves more into the circuits than this book. A good next step from here.

Frenzel LE. *Crash course in electronics technology*. 2nd ed. Newnes/Elsevier; 1996. Out of print now but still available in the used market. A programmed introduction to electronics.

Frenzel LE. *Crash course in digital technology*. 2nd ed. Newnes/Elsevier; 1998. Out of print now but still available in the used market. A programmed introduction to digital circuits. Getting a bit dated now but still valid.

Frenzel LE. *Crash course in PC and microcontroller technology*. Newnes/Elsevier; 1999. Out of print now but still available in the used market. A programmed introduction to micros. Getting dated but the fundamentals are still good.

Frenzel LE. *Principles of electronic communications systems*. 4th ed. McGraw-Hill; 2016. Recently updated and it takes the systems approach to the subject. A college text but very readable.

Frenzel LE. *Contemporary Electronics: Fundamentals, Devices and Circuits, and Systems*, McGraw Hill, 2014. A college textbook covering DC, AC, semiconductors, and linear circuits with a systems emphasis.

Horowitz P, Hill W. *The art of electronics*. 3rd ed. Cambridge University Press; 2015. Recently updated, a good example of how to present electronics. A great reference. A lab manual is also available.

Kuphaldt, TR. *Lessons in electric circuits*. Self-published; 2000–2009. A complete electronics book online and free for download. It covers DC and AC circuits, semiconductors and basic circuits, and digital. A lab manual is available. Go to www.openbookproject.new/electricCircuits.

Maxfield C. *Bebop to the Boolean Boogie*. 3rd ed. Newnes/Elsevier; 2009. First published in 1995, it was a hit. A great introduction to digital practice and circuits.

Appendix B

Projects Parts List

PARTS SOURCES

These are recommended but there are others.

Adafruit: www.adafruit.com
All Electronics: www.allelectronics.com
Digi-Key: www.digikey.com
Jameco: www.jameco.com
Marlin P. Jones & Associates: www.mpja.com
Mouser: www.mouser.com
SparkFun: www.sparkfun.com

CHAPTER 2

Digital multimeter (DMM). Must measure DC and AC voltages, DC current, and resistance. More expensive models may measure capacitance and test transistors, but these are not necessary for the projects in this book.

CHAPTER 3

- Batteries, four AA cells or a 9V battery
- Battery holder for AA cells (Get one with preconnected cells and an off/on switch. Jameco 216187 is recommended. In fact, buy two as you will need another supply for later projects.)
- Battery clip for 9-V battery (Buy two as you will need another supply later.)
- Breadboarding socket (Buy the larger one for more complex circuits. Two is recommended.)
- #22 solid copper hook up wire, insulated (At least several feet for future uses.)
- LED, any generic type or color
- 220-Ω ¼-W resistor
- 330-Ω ¼-W resistor
- 100k-Ω ¼-W resistor
- 100-µF electrolytic capacitor, voltage rating >10V

- MOSFET transistor IRF510, 2N7000, or equivalent
- Tools: soldering iron (25–35 W), rosin core solder, side cutters, wire strippers

Note: If you plan to do the projects in this book, you will need multiple values of resistors. Most parts vendors offer assortments of the most common value resistors with 5 or 10 of each value. This is a highly recommended purchase as it will save time and be more convenient.

CHAPTER 4

Project 4.1

Recommended kit is the dual adjustable regulated power supply from Jameco: Model JE215 (20626).

Project 4.2

Recommended VI packages:

- Digilent Analog Discovery or Analog Discovery 2 with Waveforms software
- National Instruments' my DAQ with LabVIEW software
- Velleman PCSU1000 oscilloscope or PCSGU250 oscilloscope with signal generator

Project 4.3

Possible power supply choices:

- Dual adjustable regulated power supply kit from Jameco: Model JE215 (20626)
- Batteries: Two each 4-AA cells in a holder (6V) or two 9-V batteries with clips
- Power supplies in VI units
- Wall adapter AC to DC power supplies, regulated preferred, 5V

Project 4.4

Parts for Fig. 4.26:

- AC to AC wall adapter transformer: 5V (Cut the connector off the cable and tin the wires with solder to plug into the breadboarding socket.)
- 1k-Ω potentiometer (Get the kind that plugs into the breadboarding socket.)

Parts for Fig. 4.27:

- 555 timer IC 8 pin dual inline package (DIP)
- 10k-Ω ¼-W resistors (3)
- 0.05-μF ceramic capacitor
- 0.1-μF ceramic capacitor
- 47-μF electrolytic or tantalum capacitor, voltage > 10V

Project 4.5

Parts for Fig. 4.31:

Same as for Fig. 4.27 but add:

- 100-Ω ¼-W resistor
- 2-in., 8-Ω speaker

Parts for Fig. 4.32:

Same as for Fig. 4.27 but add:

- 220-Ω ¼-W resistor
- LED

Project 4.7

Parts for Fig. 4.33:

Same as for Fig. 4.26 plus:

- 1N4001 silicon diode
- 1000-μF electrolytic capacitor, 16V or higher
- 0.33-μF capacitor
- 0.1-μF capacitor
- 1k-Ω, ¼-W resistor
- 7805 linear regulator, TO-220 package

Project 4.8

Parts for Fig. 4.35:

- TL081 op amp or equivalent (741, etc.)
- 15k-Ω, ¼-W resistor
- 4.7k-Ω, ¼-W resistor
- 1k-Ω pot

Parts for Fig. 4.36:

- TL081 op amp or equivalent (741, etc.)
- 6.8k-Ω, ¼-W resistor
- 1k-Ω, ¼-W resistor
- 1k-Ω pot
- Wall transformer

CHAPTER 5

Project 5.2

Parts for Fig. 5.31:

- 5V power supply as suggested in Project 5.11
- 74HC00 quad NAND gate IC
- 220-Ω, ¼-W resistor

Continued

Project 5.2—cont’d

- LED

Parts for Fig. 5.32:

- Same as parts for Fig. 4.32.
- Same as parts for Fig. 5.31.

Project 5.3

Parts for Fig. 5.33:

Same as parts for Fig. 4.32, plus:

- 74HC161 binary counter IC
- LEDs (4)
- 330-Ω, ¼-W resistors (4)
- 1k-Ω ¼-W resistors (4)
- 0.01-μF capacitor

CHAPTER 7

Project 7.6

Parts for Fig. 7.23:

- Two 6 or 9V supplies
- Part for 555 timer circuit same as for Fig. 4.32
- Radiometrix TX3A transmitter
- Radiometrix RX3A receiver
- 2N3904 NPN transistor
- 470-Ω, ¼-W resistor
- 10k-Ω, ¼-W resistor (2)
- 27k-Ω, ¼-W resistor
- LED

CHAPTER 12

Project 12.2

Parts for Fig. 12.31:

- LM393 quad comparator IC
- IRF510 MOSFET or equivalent
- 10k-Ω thermistor
- 12-V DC fan, 2 or 3 in. in diameter
- 10k-Ω, ¼-W resistors (2)
- 22k-Ω, ¼-W resistors (2)
- 50-Ω, 5-W resistor

CHAPTER 13

Project 13.1

Sources of microcontrollers:

Adafruit: www.adafruit.com
Arduino: www.arduino.c
Jameco: www.jameco.com
Marlin P. Jones & Associates, www.mpja.com
Mouser: www.mouser.com
Parallax: www.parallax.com
PICAXE: www.pickaxe.com
SparkFun: www.sparkfun.com

Project 13.2

Parts to flash an LED:

- Standard LED
- 470-Ω, ¼-W resistor

Project 13.3

Parts for pushbutton control of an LED:

- Standard LED
- Pushbutton switch with leads to plug into a breadboarding socket
- 470-Ω, ¼-W resistor
- 10k-Ω, ¼-W resistor

CHAPTER 14

Project 14.1

Acquire a soldering iron and some solder. A model with a 20–30W rating with a narrow tip is best. The solder should be 60/40 rosin core. A desoldering tool or braid is an option. Also get basic tools such as wire strippers, needle nose pliers, and side cutters. A knife is also handy.

Project 14.2

- 9-V battery clip and/or four AA cell holder
- #22 solid insulated hook up wire

Project 14.3

Acquire the solder practice kit (SP-1A) or some other kit to practice with.

This page intentionally left blank

Appendix C

Learning Resources

This book provides a good introduction to electronics. But as you will find out, the more you learn the more you realize what you do not know. Most people want to learn more.

Today, most people learn from the Internet. With searches you can find information on almost anything you want to learn. Wikipedia is an example. Listed here are some additional sources that I recommend for your continued learning.

- *All About Circuits* is an online resource for electronic engineers and enthusiasts that offers a wide range of materials including design calculators, articles, textbooks, and projects (http://www.allaboutcircuits.com/tools/).
- *MOOCs* or *Massive Open Online Courses* are online college-level courses covering an extensive array of topics. Many are free; others are low cost. The offerings are extensive so you need to do a search on each website to find what you want. The following are leading providers of MOOCs:
    - Coursera: www.coursera.com
    - EdX: www.edx.com
    - Udemy: www.udemy.com
    - MOOCs listing: www.mooc-list.com
    - MOOCs directory: www.moocs.co
- The *Great Courses* is a source of excellent video courses on DVD, CD, or online. They offer a general electronics course called Understanding Modern Electronics by Professor Richard Wolfson of Middlebury College. Its price varies with discounts offered. Other courses of potential interest are those on science and math (www.thegreatcourses.com).
- EEWeb is a website offering a variety of free electronic tools and calculators. The tools include schematic capture, PCB design and calculations, RF design tools, and passive components calculators. Other features are an online scientific calculator, graph paper and math tools for algebra, trig and calculus (https://www.eeweb.com/toolbox).
- Radio Electronics is a website with an extensive collection of articles and tutorials about all aspects of electronics (www.radio-electronics.com).
- Kahn Academy is a free online learning site offering courses in math, electrical engineering, and programming (www.kahnacademy.com).

Electronic Engineering

ELECTRONICS EXPLAINED

Fundamentals for Engineers, Technicians, and Makers

Second Edition

Louis E. Frenzel Jr.

Take a fresh, systems based approach to understanding how electronics work!

Electronics Explained takes a systems based approach to the fundamentals of electronics, covering the different types of electronic circuits, how they work, and how they fit together to create modern electronic equipment, enabling you to apply, use, select, operate and discuss common electronic products and systems.

This new edition has been updated to show the latest technological trends with added coverage of:

- Internet of Things (IoT)
- Machine-to-Machine (M2M) technology
- Ethernet to 100 Gb/s
- Wi-Fi, Bluetooth, and other wireless technologies
- 5G New Radio cellular standards
- Microcontrollers and programming with the Arduino, BASIC Stamp, and others

With this book you will:

- Learn about the basic components of electronics such as resistors, capacitors, inductors, transformers, diodes, transistors, and integrated circuits.
- Discover different types of circuits, using the functional block diagram approach which makes it easy to understand their purpose and application.
- Get involved with Hands-On projects in each chapter, using components and ICs with the breadboarding socket.

About the author

Louis E. Frenzel Jr. has been a Technology Editor with Electronic Design magazine since 2000 and covers the wireless, communications, and networking and test/measurement fields Lou has over 30 years of electronic industry experience as an engineer in the geophysical, aerospace and computer fields. Prior to joining ED he was a college professor teaching electronics and semiconductor manufacturing and working on several NSF grants. He holds bachelors and masters degrees and is author of 21 books on communications, computers and electronics.

(57) **ABSTRACT**

A device collects electrostatic charge from the atmosphere and stores the electrostatic charge for further use. The device includes a primary array including a plurality of electrically-conducting collectors, a plurality of electrically-conducting inductors, a charge regulator, and a charge storage device. A secondary array can be added to improve the efficiency of the primary array.

METHOD AND DEVICE FOR COLLECTING ELECTROSTATIC CHARGE FROM THE ATMOSPHERE

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of Provisional Application No. 61/408,973 filed Nov. 1, 2010, the contents of which are incorporated herein by reference.

BACKGROUND OF THE INVENTION

The present invention generally relates to a method and apparatus for collecting excess electrostatic charge from the environment. More specifically, the present invention relates to a method and apparatus for collecting excess electrostatic charge from the environment and storing the electrostatic charge for dispersal or further use.

The buildup of static electricity frequently occurs in many different natural and commercial environments. People and objects may build up a high voltage charge. In addition, the air may acquire an undesirable charge. Unfortunately, when a person gets close to another person and/or an object, the difference in the voltage charge produces an undesirable discharge in the form of a spark. Sparks may be lethal to individuals and sensitive machines in some industrial environments.

Current devices for electrostatic charge collection typically rely on electrically-powered systems which operate at high voltages and are ineffective in actually collecting ion charges for controlled dispersal.

As can be seen, there is a need to provide a reliable device for electrostatic charge collection that operates at low voltage.

SUMMARY OF THE INVENTION

In one aspect of the present invention, a device for collecting electrostatic charge includes an array having a plurality of electrically-conducting collectors to collect the electrostatic charge, a plurality of electrically-conducting inductors electrically coupled to the electrically-conducting collectors, a charge regulator coupled to the electrically-conducting inductors, a charge storage device coupled to the charge regulator, a plurality of brushes for transferring collected electrostatic charge from the electrically-conducting collectors to the charge storage device; and a plurality of charge equalization wires coupled to the plurality of brushes.

In another aspect of the present invention, a second collector/inductor assembly can be connected to the first collector/inductor assembly, where each assembly includes an array having a plurality of electrically-conducting collectors to collect the electrostatic charge, a plurality of electrically-conducting inductors electrically coupled to the electrically-conducting collectors, a plurality of brushes for transferring collected electrostatic charge from the electrically-conducting collectors to the charge storage device; and a plurality of charge equalization wires coupled to the plurality of brushes.

These and other features, aspects and advantages of the present invention will become better understood with reference to the following drawings, description and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** illustrates a perspective front view of a device for collecting electrostatic charge from the atmosphere according to an exemplary embodiment of the present invention showing a primary assembly and a secondary assembly;

FIG. **2** illustrates a perspective top view of a device for collecting electrostatic charge from the atmosphere according to another exemplary embodiment of the present invention;

FIG. **3** illustrates a side view of the device of FIG. **2**; and

FIG. **4** illustrates a top view of the device of FIG. **2**.

DETAILED DESCRIPTION OF THE INVENTION

The following detailed description is of the best currently contemplated modes of carrying out exemplary embodiments of the invention. The description is not to be taken in a limiting sense, but is made merely for the purpose of illustrating the general principles of the invention, since the scope of the invention is best defined by the appended claims.

Various inventive features are described below that can each be used independently of one another or in combination with other features.

Broadly, embodiments of the present invention generally provide a rotating device for collecting electrostatic charge from the atmosphere and storing the electrostatic charge for dispersal or further use.

FIGS. **1** and **2** illustrates the device **10** for collecting electrostatic charge including an array having a plurality of electrically-conducting collectors **12** to collect the electrostatic charge, a plurality of electrically-conducting inductors **14** electrically coupled to the electrically-conducting collectors **12**, a charge regulator **26** coupled to the electrically-conducting inductors **14**, a charge storage device **28** coupled to the charge regulator **26**, a plurality of brushes **22** for transferring collected electrostatic charge from the electrically-conducting collectors **12** to the charge storage device **28**; and a plurality of charge equalization wires **24** coupled to the plurality of brushes **22**.

FIG. **1** illustrates an alternative embodiment of the present invention in which the device **10** may include a primary collector/inductor assembly **16** and a secondary collector/inductor assembly **18** mounted on a common shaft **20**. In one embodiment, the primary collector/inductor assembly **16** and secondary collector/inductor assemblies **18** may be directly connected by using rotational bearing assemblies attached to each end of the primary collector/inductor assembly **16** and the secondary collector/inductor assembly **18**.

The collectors **12** may have different shapes. In one embodiment, the collectors **12** may have a cylindrical, rectangular, pyramidal, planar, or elongated shape. The collectors **12** may be placed parallel to each other and arranged at approximately equal distances from an axis of rotation of their aggregate collector/inductor assemblies **16** and **18**. In one embodiment, the collectors **12** may be made of metal, composites, alloys, graphite, or any other conductive materials. The collectors **12** may have a solid body or a hollow body.

The exemplary invention embodiment shown as device **10** may include a plurality of inductors **14**. The inductors **14** may be operatively connected to the collectors **12** to extract charged ions from the ambient environment. In one embodiment, the inductors **14** may have a length greater than twice the radius of rotation of the rotating array with the plurality of conductors **12**.

The charge regulator **26** may be a standard commercially-available charge regulator. In one embodiment, the charge regulator **26** may be a spark gap. The charge regulator **26** may include electrical components that limit the voltage build-up in the rotating device **10** and the charge storage device **28**.

A plurality of brushes or brush equivalents **22** may be used to transfer accumulated charges between the collectors **12** and inductors **14** during the operation of the device **10**. The number of brushes **22** may be determined by the implemented configuration. In one embodiment, the device **10** may include four brushes **22**.

The charge equalization wire **24** may momentarily connect two of the collectors **12** under the influence of two inductors **14**. This wire may allow the transfer of charge between oppositely-charged collectors **12** at appropriate times in the collector assembly **16** during the operation of the device **10**.

When the collector **12** and inductor **14** assemblies of the device **10** are counter-rotated relative to each other by any appropriate means, the ion extraction process may be a normal result of the rotation of the device **10**. The collection and removal of the charge may be achieved by the unique combination of accepted electrostatic engineering principles and the new component configuration to create an electrostatic collection system which may be capable of low-voltage electrostatic ion collection capabilities.

The device **10** may be placed in a selected environment which contains excess electrostatic charge. The operation of the device **10** may be initiated by applying mechanically rotational power to the collector and/or inductor assemblies **12** to initiate the charge collection process, which continues until the rotation stops. The resulting operation may cause a transfer of the excess charge to the charge storage device **28** where it can be immediately dispersed and/or collected.

The elements of the device **10** may be in a number of different configurations which may operate at different efficiencies. The size, shape, physical relationships, and materials employed may be configured to have an apparently different appearance when actually they are alternative implementations of this invention.

The device **10** adapted to rotate for collecting electrostatic charge may be considered to be based on classic electrostatic accumulation principles, but is configured to operate at significantly lower voltages, thus requiring fewer operating components. These improvements may allow major simplifications in the construction and maintenance of the device **10** and its associated systems, reducing initial production costs, operational power requirements, and ongoing maintenance costs.

The present invention has been successfully demonstrated at the bench-scale level.

It should be understood, of course, that the foregoing relates to exemplary embodiments of the invention and that modifications may be made without departing from the spirit and scope of the invention as set forth in the following claims.

I claim:

1. A device for collecting electrostatic charge comprising:

a primary assembly, wherein the primary assembly includes;

an array having a plurality of electrically-conducting collectors to collect the electrostatic charge;

a plurality of electrically-conducting inductors electrically coupled to the electrically-conducting collectors;

a primary charge regulator coupled to the primary assembly electrically-conducting collectors;

a charge storage device coupled to the charge regulator;

a plurality of brushes for transferring collected electrostatic charge from the electrically-conducting collectors to a charge storage device; and

a plurality of primary assembly charge equalization wires coupled to the plurality of primary assembly brushes; and

a secondary assembly electrically connected to the primary assembly, wherein the secondary assembly includes:

an array having a plurality of secondary assembly electrically-conducting collectors to collect electrostatic charge;

a plurality of secondary assembly electrically-conducting inductors electrically coupled to the secondary assembly electrically-conducting collectors;

a secondary charge regulator electrically coupled to the secondary assembly electrically-conducting collectors and the primary assembly electrically-conducting collectors;

a plurality of brushes for transferring collected electrostatic charge from the secondary assembly electrically-conducting inductors to the secondary assembly electrically-conducting collectors; and

a plurality of secondary assembly charge equalization wires coupled to the plurality of secondary assembly brushes.

2. The device according to claim **1**, wherein the sizes of the primary and secondary assemblies are different from each other.

3. The device according to claim **1**, wherein the primary and secondary assemblies are mounted and rotated on the same shaft.

4. The device according to claim **1**, wherein the primary and secondary assemblies are mounted and rotated on separate shafts.

5. The device according to claim **1**, wherein the primary assembly collector array and the secondary assembly collector array do not rotate.

6. The device according to claim **1**, wherein the primary assembly inductor array and the secondary assembly inductor array rotate.

[57] ABSTRACT

Two inversely ganged variable capacitors having a common movable element varying the capacities such that when one capacitor is at maximum capacitance, the other is at minimum capacitance, have, after initially charging, a substantially constant contained or trapped charge distributed between the two capacitors. As the capacities of the capacitors are varied, a potential difference is developed between the fixed plate of one capacitor and the fixed plate of the other. When these two potential points are connected to a load, charge is transferred from one capacitor to the other as a current flow through the load. The total charge is not diminished, the energy supplied the load being the energy expanded on moving the movable charged plates. As the movable plates are moved in a cyclic manner an alternating current is provided to the load.

THE INVENTION

ELECTROSTATIC ENERGY CONVERSION SYSTEM

RIGHTS OF THE GOVERNMENT

The invention described herein may be manufactured and used by or for the Government of the United States for all governmental purposes without the payment of any royalty.

BACKGROUND OF THE INVENTION

The field of the invention is in electrostatic machines.

Electrostatic machines have been well known for many years. The Toepler-Holtz and the Wimshurst machines were early electrostatic generators. Now their usage is mainly for demonstrations in the Physics Laboratory. The only remaining electrostatic machine to remain in extensive usage is the Van de Graaff type electrostatic generator. It is presently used to generate extremely high voltage potentials for atomic research. Substantially all of the prior art devices are direct current type machines.

The following publications may be helpful in further understanding the art. Electrostatic Sources of Electric Power, John G. Trump, Electrical Engineering, Vol. 66, No. 6, June 1947, pages 525-534; U.S. Pat. No. 2,810,878 to patentee N. Felici, and U.S. Pat. No. 3,094,653 to patentees D. B. LeMay et al.

SUMMARY OF THE INVENTION

An ac electrostatic variable capacity energy conversion system utilizing a fixed contained charge functions as an electrical generator when mechanically driven or as a motor providing mechanical shaft power when electrically driven.

BRIEF DESCRIPTION OF THE DRAWING

FIG. 1 is a simplified pictorial-schematic diagram representative of a rotational generator embodiment of the invention;

FIG. 2 is a simplified pictorial schematic diagram representative of a reciprocally driven generator embodiment of the invention;

FIG. 3 is an electrical schematic diagram of the embodiment illustrated in FIG. 2;

FIG. 4 is a schematic diagram illustrative of the electrical charges and capacitances of the embodiment physically illustrated in FIG. 1;

FIG. 5 is a pictorial-schematic representation of an embodiment of the invention wherein the load is between dielectric materials;

FIG. 6 is a schematic diagram of the system shown in FIG. 5 illustrative of the charges and capacitances;

FIG. 7 is a schematic diagram of a pulsed energy input embodiment of the invention in State A;

FIG. 8 is the same embodiment except in State B;

FIG. 9 is the same embodiment except in State C;

FIG. 10 is the same embodiment except in State D;

FIG. 11 is a schematic representation of an embodiment of the invention having pulsed energy input with the generators indirectly connected to the load through dielectric material, in State A;

FIG. 13 is the same embodiment of FIG. 11 except in State C;

FIG. 14 is the same embodiment of FIG. 11 except in State D;

FIG. 15 is a schematic diagram of an embodiment of the invention having continuous mechanical input providing a continuous wave (cw) electrical output with the generators directly connected to the load;

FIG. 16 is a schematic diagram of an energy conversion system of the invention wherein the system functions as a motor receiving electrical energy and delivering mechanical energy;

FIG. 17 is a pictorial-block-schematic diagram of an embodiment of the invention for receiving rotational energy from a mechanical source and delivering electrical energy to a load;

FIG. 18 is a schematic drawing shown a control system for maintaining a given maximum and minimum charge on the generating capacitors; and

FIG. 19 is a block-schematic diagram showing the improvement of the disclosed invention over a typical prior art system.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In embodiments of the invention, energy conversion is obtained for the Variable Capacitance Electrostatic Energy Conversion System by operation of variable capacitance electrostatic generators, involving contained charge, in paired opposition to one another across the load (or electrical source of power), either directly or indirectly through dielectric material, to provide for conversion of mechanical energy to electrical energy (or electrical energy to mechanical energy).

For a variable capacitance electrostatic generator, the electrical power input to the capacitor, P_e (watts), is equal to the increase in capacitor electrostatic field energy, W_{ef} (joules), per unit time, t (seconds), and the mechanical power output, P_M (watts):

$$P_e = (dW_{ef}/dt) + P_M$$

with

$P_e = Vdq/dt$

V = capacitor potential (volts)

q = charge on capacitor (coulombs)

and $W_{ef} = \frac{1}{2} CV^2$

C = capacitor capacitance (farads)

Also, $q = CV$

Therefore, $P_M = \frac{1}{2} V^2 (dC/dt)$

and the time rate of conversion of mechanical to electrical energy, dW_{ME}/dt, equal to $-P_M$, is given as

$$dW_{ME}/dt = -\tfrac{1}{2} V^2 (dC/dt)$$

Conversion of mechanical shaftpower to electrical power to a load by variable capacitance electrostatic generators operating in paired opposition to one another across the load (and involving contained charge) shall be considered first.

Examples of two specific physical arrangements of electrostatic generators operating in paired opposition to one another connected directly to a load R (ohms) are shown in FIGS. 1 and 2. Capacitance change is by rotary motion in the embodiment of FIG. 1 and reciprocating motion for the embodiment represented by FIG. 2. FIG. 2 is shown in partial schematic form in FIG. 3 and the electrical schematic diagram for the device of FIG. 1 is shown in FIG. 4. Referring to FIGS. 1 and 4, the capacitors 11 and 12 each range in value from high capacitance C_H to low capacitance C_L and are coupled by the drive shaft 13 so that they operate in opposition to each other; that is, when one capacitor has value C_H, the other capacitor has value C_L, and vice versa. The capacitors each are initially charged to possess a charge Q, and hence there exists a contained (or "trapped") charge of 2Q for the system. As variable capacitor **11** varies from C_H to C_L, its charge varies from $(Q + q_o)$ to $(Q - q_o)$; as variable capacitor **12** varies from C_L to C_H, its charge varies from $(Q - q_o)$ to $(Q + q_o)$. A charge $2q_o$ is directly transferred across the load **14**. As capacitor **11** is decreasing in capacitance mechanical energy is converted by it to electrical energy and electrical energy is converted to mechanical energy by variable capacitor **12** which is increasing in capacitance. However, since capacitor **12** is drive-shaft coupled to capacitor **11**, this mechanical energy may be considered as simultaneously reconverted to electrical energy. With rotation, capacitor **11** reaches the state initially occupied by capacitor **12** and capacitor **12** is now in the state initially occupied by capacitor **11**. As the drive shaft continues to rotate, the capacitors return to their respective initial states with another transfer of charge $2q_o$ across the load, and a cycle is completed.

A schematic-pictorial physical arrangement of the electrostatic generators operating in paired opposition to one another, indirectly connected to the load through dielectric (insulating) material, is shown in FIG. **5**; an electrical schematic diagram for this embodiment is shown in FIG. **6**. The advantages of using a dielectric as electrode material is well known as exemplified by U.S. Pat. No. 3,745,481 to patentees G. F. Erickson et al. In this embodiment for each cycle a charge of $4q_o$ is transferred by displacement across the load; there is charge q_o associated with the dielectric material capacitors of capacitance c_d.

The simplified embodiments presented above were for initial explicit exposition of the concept involved for the Energy Conversion System. The following embodiments, presented in more detail, will explain the operation of the system and aid in the comprehension of the invention.

The pulsed energy input systems with the generators directly connected to the load are perhaps the easiest to comprehend. The electrical schematic diagram of these embodiments is shown in FIG. **7**. It is similar to the electrical schematic diagram of previous FIG. **4** except for the added switch **20**. The pictorial diagram of FIG. **1** is also a suitable physical representation if a switch is placed in the line going to the load. The operation will be explained considering four states or positions of the capacitors after a movement from their prior state. It is assumed that the capacitors have been initially charged and that operation through previous cycles has taken place. The switch is triggered cyclicly as a function of drive shaft position.

State A (FIG. **7**): Capacitor **21** has capacitance C_H and a charge $(Q + q_o)$; capacitor **22** has capacitance C_L and a charge $(Q - q_o)$; the potentials (volts) across the capacitors are equal. (NOTE: The magnitude of the potentials associated with the various circuit elements are indicated by the relative length of the arrows in the schematics as presented in the figures, e.g., arrows **23** and **24**, with the tip of the arrow indicating the direction of increasing potential for the charge; the arrows, representing the potential, are not necessarily drawn to scale.) The switch is in closed position; the switch, for the purpose of this exposition, shall be considered as an ideal switch (that is, it has negligible inductance, infinitely small capacitance relative to other circuit elements, infinite resistance when open, and zero resistance when closed). The potential across a capacitor is equal to the charge on the capacitor divided by its capacitance, therefore;

$$(Q + q_o)/C_H = (Q - q_o)/C_L$$

The energy associated with the electrostatic field of a capacitor is given by one-half the value of its charge squared, divided by its capacitance. Therefore, the total electrical energy of the electric circuit in State A, W_A, is given as

$$W_A = \tfrac{1}{2}(Q + q_o)^2/C_H + \tfrac{1}{2}(Q - q_o)^2/C_L$$

The switch is opened and, as the drive shaft rotates, the capacitances of capacitors **1** and **2** change to State B.

State B (FIG. **8**): Capacitor **21** now has capacitance C_L and capacitor **22** has capacitance C_H. The total electrical energy for the electric circuit in State B, W_B, is given as

$$W_B = \tfrac{1}{2}(Q + q_o)^2/C_L + \tfrac{1}{2}(Q - q_o)^2/C_H$$

The potential rise across capacitor **21** is equal to the potential drop across the switch **20** and across capacitor **22**.

State C (FIG. **9**): The switch **20** is now closed. The potential rise across capacitor **21** is now equal to the potential drop across the load and the potential drop across capacitor **22**. It is assumed, for the purpose of this exposition, that the transient response time of the electric circuit is much faster than the time required for one complete cycle of the variable capacitors (that is, the time required for the variable capacitors, starting at respective initial states, to return to those respective states, as the drive shaft rotates). With q now representing the charge being transferred, the equation for the electrical circuit response is given as

$$(Q + q_o - q)/C_L = R\,(dq/dt) + (Q - q_o + q)/C_H$$

When $t = 0$, $q = 0$; when $t = \infty$, $q = 2q_o$.
The solution of the previous equation is as follows:

$$q = 2q_o[1 - \exp[-(1/R)\,(1/C_L + 1/C_H)t]]$$

And from the earlier equation $(Q + q_o)/C_H = (Q - q_o)/C_L$

$$q_o = \frac{(1/C_L - 1/C_H)}{(1/C_L + 1/C_H)}\,Q$$

State D (FIG. **10**): After charge rearrangement by a flow of current through the load, capacitor **22** is in the same state as capacitor **21** in State A; capacitor **21** is in the same state as capacitor **22** in State A; and the total electrical energy for the electrical circuit in State D, W_D, is given as

$$W_D = \tfrac{1}{2}(Q + q_o)^2/C_H + \tfrac{1}{2}(Q - q_o)^2/C_L$$

By subtracting this equation from the one in State B, it is seen that:

$$W_B - W_D = 2q_o^2\,(1/C_L + 1/C_H) = 4[\tfrac{1}{2}\,q_o^2(1/C_L + 1/C_H)]$$

-continued

$$\int_{o}^{\infty} R\left(\frac{dq}{dt}\right)^2 dt = 2q_o^2(1/C_L + 1/C_H) = W_B - W_D$$

Electrostatic energy is delivered to the load. As the drive shaft **25** rotates, capacitors **21** and **22** will again go through States B and C, with their roles interchanged, until the capacitors return to their respective states as given in State A. For this second half of the cycle, the same amount of energy is delivered to the load as was delivered in the first half of the cycle; hence, the energy delivered to the load per cycle, W, is given as follows:

$$W = 2(W_B - W_D) = 8[\tfrac{1}{2}\, q_o{}^2(1/C_L + 1/C_H)]$$

The limit on energy transfer may be determined as follows. The breakdown potential for the variable capacitors, V_{CB} (volts), may be related to the charge on the variable capacitors:

$$(Q + q_o)/C_L = V_{CB}$$

By use of this equation and the one given at the end of State C, the limiting value of q_o may be given as follows:

$$q_o = (C_L/2)\,(1 - C_L/C_H)V_{CB}$$

By substitution of the above value of q_o into the foregoing equation for W, the limit on W, W_{CB}, is given as

$$W_{CB} = (1 + C_L/C_H)\,(1 - C_L/C_H)^2 C_L V_{CB}{}^2$$

The range of W is then given as follows: $0 \leqq W < W_{CB}$

For non-negligible circuit inductance, such as, for example, a series inductance L (henries), the equation for the electrical circuit response is given as

$$(Q + q_o - q)/C_L = R(dq/dt) + L(d^2q/dt^2) + (Q - q_o + q)/C_H$$

When $t = 0$, $q = 0$; when $t = \infty$, $q = 2q_o$; the solutions are given as follows.

For over damped response, $(R/2L)^2 > (1/L)\,(1/C_L + 1/C_H)$,

$$q = 2Q\left[\frac{C_H - C_L}{C_H + C_L}\right]\left[1 - \exp\left(-\frac{Rt}{2L}\right)\left[\frac{R}{2La}\sinh(at) + \cosh(at)\right]\right]$$

With

$$a = \sqrt{\left(\frac{R}{2L}\right)^2 - \frac{1}{L}\left(\frac{1}{C_L} + \frac{1}{C_H}\right)}$$

For critically damped response, $(R/2L)^2 = (1/L)\,(1/C_L + 1/C_H)$,

$$q = 2Q\left[\frac{C_H - C_L}{C_H + C_L}\right]\left[1 - \exp\left(-\frac{Rt}{2L}\right) - \frac{Rt}{2L}\exp\left(-\frac{Rt}{2L}\right)\right]$$

For under damped response, $(R/2L)^2 < (1/L)\,(1/C_L + 1/C_H)$,

$$q = 2Q\left[\frac{C_H - C_L}{C_H + C_L}\right]\left[1 - \exp\left(-\frac{Rt}{2L}\right)\left[\frac{R}{2Lb}\sin(bt) + \cos(bt)\right]\right]$$

With b being given by a, as defined above, divided by the square root of minus one. The relation between Q and q_o is

$$q_o = \frac{(1/C_L - 1/C_H)}{(1/C_L + 1/C_H)}\,Q.$$

as previously stated.

An embodiment of the invention for operation with pulsed energy input and the electrical load connected through dielectric material, such as barium titanate, is schematically illustrated in FIG. **11**. This type of system is ideally suited for the production of molecular excitation and volume ionization of high-pressure lasing media. As in the previous embodiment, four states or end positions of arcs of rotational movement will be illustrated.

State A (FIG. **11**): Capacitor **31** has capacitance C_H and a charge $(Q + q_o)$; capacitor **32** has capacitance C_L and a charge $(Q - q_o)$. The potential rise across capacitor **32** is equal to the sum of the potential drops across each dielectric electrode (**33** and **34**, each of capacitance c_d) and capacitor **31**:

$$(Q - q_o)/C_L = 2q_o/c_d + (Q + q_o)/C_H$$

The total electrical energy of the electric circuit in State A is given as follows:

$$W_A = \tfrac{1}{2}\,(Q + q_o)^2/C_H + q_o{}^2/c_d + \tfrac{1}{2}\,(Q - q_o)^2/C_L$$

Switch **36** is opened and, as drive shaft **35** rotates, the capacitance of capacitors **31** and **32** changes, and state B is reached.

State B (FIG. **12**): Capacitor **31** now has capacitance C_L and capacitor **32** has capacitance C_H. The total electrical energy for the electric circuit in State B is given as follows:

$$W_B = \tfrac{1}{2}\,(Q + q_o)^2/C_L + q_o{}^2/c_d + \tfrac{1}{2}\,(Q - q_o)^2/C_H$$

The potential rise across capacitor **31** and the two capacitances c_d equals the potential drop across the switch and capacitor **32**.

State C (FIG. **13**): Switch **36** is now closed. The potential rise across capacitor **31** and the two capacitances c_d equals the potential drop across the load and capacitor **32**. The equation for the electrical circuit response is given as follows:

$$(Q + q_o - q)/C_L + 2(q_o - q)/c_d = R(dq/dt) + (Q - q_o + q)/C_H$$

When $t = 0$, $q = 0$; when $t = \infty$, $q = 2q_o$.

Solution of the equation is as follows:

$$q = 2q_o[1 - \exp[-(1/R)\,(1/C_L + 2/c_d + 1/C_H)t]]$$

With, as given previously,

$$q_o = \frac{(1/C_L - 1/C_H)Q}{(1/C_L + 2/c_d + 1/C_H)}$$

State D (FIG. **14**): After charge rearrangement, capacitor **32** is in the same state as capacitor **31** in State A; capacitor **31** is in the same state as capacitor **32** in State A; and the polarity of the charge on the dielectric capacitances has been reversed. The total electrical energy for the electric circuit in State D is given as follows:

$$W_D = \tfrac{1}{2}(Q + q_o)^2/C_H + q_o^2/c_d + \tfrac{1}{2}(Q - q_o)^2/C_L$$

$$(Q - q)/C_1 = R(dq/dt) + (Q + q)/C_2$$

with $q = 0$, for $t = 0$.

With sinusoidal input to the load, for the following assumed capacitance:

$$C_1 = \frac{1}{\frac{1}{C_H} + (\frac{1}{C_L} - \frac{1}{C_H})[\frac{1 - \cos\frac{2\pi}{T}(t + \frac{T}{4})}{2}]}$$

$$C_2 = \frac{1}{\frac{1}{C_H} + (\frac{1}{C_L} - \frac{1}{C_H})[\frac{1 + \cos\frac{2\pi}{T}(t + \frac{T}{4})}{2}]}$$

$$q = \frac{\frac{Q}{R}[\frac{1}{C_L} - \frac{1}{C_H}]}{\sqrt{(\frac{2\pi}{T})^2 + [\frac{1}{R}(\frac{1}{C_L} + \frac{1}{C_H})]^2}} X$$

$$\left[\begin{array}{l} \cos[\frac{\pi}{2} - \arctan([\frac{2\pi}{T}]/[\frac{1}{R}(\frac{1}{C_L} + \frac{1}{C_H})])]\exp[-\frac{1}{R}(\frac{1}{C_L} + \frac{1}{C_H})t] \\ -\cos[\frac{2\pi}{T}(t + \frac{T}{4}) - \arctan([\frac{2\pi}{T}]/[\frac{1}{R}(\frac{1}{C_L} + \frac{1}{C_H})])] \end{array}\right]$$

By combining equations, it is seen that:

$$W_B - W_D = 2q_o^2(1/C_L + 2/c_d + 1/C_H) = 4[\tfrac{1}{2} q_o^2 (1/C_L + 2/c_d + 1/C_H)]$$

And that:

$$\int_0^\infty R(\frac{dq}{dt})^2 dt = 2q_o^2(1/C_L + 2/c_d + 1/C_H) = W_B - W_D$$

Electrostatic energy is delivered to the load. As drive shaft **35** rotates, capacitors **31** and **32** will again go through States B and C, with their roles interchanged, until the capacitors return to their respective states as given in State A. For this second half of the cycle, the same amount of energy is delivered to the load as was delivered in the first half of the cycle; hence, the energy delivered to the load per cycle, W, is given as follows:

$$W = 2(W_B - W_D) = 8[\tfrac{1}{2} q_o^2](1/C_L + 2/c_d + 1/C_H)$$

Assuming q_o limited by the breakdown potential of the dielectric material, V_{dB}, $q_o = c_d V_{dB}$. Then, the limit on W, W_{dB}, is as follows:

$$W_{dB} = 4(c_d/C_L + 2 + c_d/C_H)c_d V_{dB}^2$$

The range of W is then given as follows: $0 \leqq W < W_{dB}$

FIG. **15** schematically illustrates an embodiment of the invention having continuous mechanical energy input and providing a continuous wave output to the loads. It is similar to previous FIG. **4** except for designations of charge and capacitance.

Consider the system schematic as shown in FIG. **15**; and, at time $t = 0$, the variable capacitors **41** and **42** have the same capacitance, the same charge Q, and hence are at the same potential. Capacitor **42** is out of phase with capacitor **41** by half a period; the capacitors vary periodically with period T (seconds).

The circuit equation for the transported charge q is as follows: assuming negligible circuit inductance:

with average power, P (watts), given, for the electrical circuit time constant,

$$1/[\frac{1}{R}(\frac{1}{C_L} + \frac{1}{C_H})],$$

much less than T, and after transient decay, as follows:

$$P = \frac{1}{T}\int_t^{t+T} R(\frac{dq}{dt})^2 dt = \frac{2\pi^2 R Q^2 (C_H - C_L)^2}{T^2 (C_H + C_L)^2}$$

and with Q limited by the breakdown potential V_{CB} of the capacitors as follows:

$$[\frac{(Q - q)}{C_1}]_{maximum} = \frac{Q(C_H + C_L)}{2C_H C_L} = V_{CB}$$

By use of these last two equations, the limit on P, P_{CB}, is:

$$P_{CB} = \frac{8\pi^2 C_H C_L (C_H - C_L)^2 V_{CB}^2}{T^2 (C_H + C_L)^3 (\frac{1}{R})(\frac{1}{C_L} + \frac{1}{C_H})}$$

The range of P is then given as follows: $0 \leqq P < P_{CB}$

As with the pulsed embodiments the load on the *cw* embodiments may be an electrostatic field between dielectric electrodes. It is also to be understood that the electrical outputs of generating embodiments of the invention, while generally of quite high electrical potential, may be rectified (and filtered), or run through a transformer effecting an impedance change, or any of the other conventional electrical changes and usages that are common practice with continuous wave or pulsed alternating current voltages.

It is also to be understood that for simplicity, only one movable and one fixed plate has been shown for a variable capacitor, and that embodiments may be constructed that have capacitors with many fixed and movable plates. A plurality of embodiments may be connected in series for providing higher output voltages and better voltage breakdown characteristics. The polarity of the charge placed on the capacitors, i.e., the common polarity of all the fixed plates of an embodiment with respect to the movable plates is immaterial.

The electrostatic energy conversion system of the invention may also be operated as a motor. FIG. **16** is a simplified schematic representation of an embodiment of the invention for receiving electrical energy from a power source **45** and providing torque to rotate shaft **48**. Variable capacitors **46** and **47** are similar to those in the generating device, with the capacitance of capacitor **46** being a maximum when the capacitance of capacitor **47** is a minimum. Shaft **48** is driven by the forces of the capacitor plates to rotate in synchronism with the frequency of source **45**. Thus, unless the frequency of source **45** is relatively slowly increased from dc to the desired operating frequency, other conventional means such as are normally used to get synchronous motors up to synchronous speed may be used to bring shaft **48** up to substantially synchronous speed with the line frequency of the source of electrical power before connection is made.

It is to be understood that the devices of the invention, generally like other electrostatic devices from a practical consideration, generally function with relatively high voltages compared to conventional electromagnetic equipment. As pointed out by Trump in the previously referenced AIEE (now IEEE) paper, two metallic plates of 100 square inches area which are parallel and insulated from each other, with an electric field of 300 volts per centimeter between them have an electrostatic force of attraction of about 0.0005 pound. If the active gradient is increased to 30,000 volts per centimeter, which is the highest voltage that can be insulated in atmospheric air, the electrostatic force between the plates is increased to little more than 0.5 pound. When the plates are immersed in a high vacuum and the gradient increased to 3 million volts per centimeter, the electrostatic force then becomes approximately 5,700 pounds.

From the foregoing, it is readily apparent that for embodiments of the invention to be practical, the variable capacitors should be operated in a high vacuum. For embodiments used in outer space, this is generally not a problem, but for terrestial embodiments, it is generally preferred that a sealed chamber having a high vacuum be used. Insulative gases such as sulphur hexafluoride or air at high pressures may be used instead of the high vacuum to provide the necessary insulation at the high voltages required for practical operation. Another reason for generally preferring the high vacuum environment for embodiments of the invention is the elimination of drag on the moving members. A complete system for the cw generation of electrical power under normal terrestial conditions is shown schematically in FIG. **17**. Variable capacitors **50** and **51**, with rotation, pass a contained charge back and forth between them causing a current to flow through load **52** delivering power to it. Driver **53** may be any suitable device that can supply the torque necessary to rotate the movable plates of the capacitors such as an electric motor, a turbine, or even a hand crank. Generally, it is desirable to provide conventional speed sensor **54** with conventional feedback control **55**, actuating energy input controller **56**, so that the frequency of the generated electrical energy supplied to load **52** is relatively constant. An initial charge is placed on variable capacitors **50** and **51** by momentarily closing switch **57** causing conventional high potential source **58** to place an equal potential charge of the same polarity on each capacitor. It is generally desirable to position the movable plates of the capacitors such that they have equal capacity when initially charged so that the initial charge magnitudes will also be equal. The capacitors are operated in a high vacuum in conventional sealed chamber **59**. Conventional vacuum pump **60** provides the high vacuum in the chamber (approximately 10^{-8} Torr). Mechanical drive shaft **61** extends through the chamber walls in magnetically sealed rotary motion feedthroughs **62** and **63**. These conventional, commercially available, sealed bearings having ferrofluid seals provide substantially zero leakage (at speeds up to 10,000 rpm) to a high vacuum on one side of the bearing seal and atmospheric pressure on the other side of the bearing. Conventional capacitor plate material such as stainless steel is suitable and generally preferable. Conventional high voltage feedthroughs **64** and **65** provide for transfer of charge from the stator capacitor plates to the load.

As previously stated, once the charge is placed on the capacitors it is not diminished or dissipated in supplying power to the load. It is a contained or trapped charge, and is not run down by the load. If the insulation within the chamber were perfect, the charge would never have to be replenished. Since nothing is perfect the charge will, over a long period of time, decrease. It may be replenished by momentarily actuating switch **57** as in the initial charging of the capacitors or the charge may be automatically held within predetermined maximum and minimum values on the capacitor plates by an electrical circuit as shown schematically in FIG. **18**. For simplicity of explanation, maximum voltage monitoring is shown on one side of the capacitor pair and minimum voltage monitoring on the other. It is to be understood that both a maximum and a minimum monitoring may be on the same side, or simultaneously on both sides, if desired. Potential source **70** and diode **71** add charge when the voltage potential of capacitor **72** is below that of source **70** when capacitor **72** is at maximum capacitance. Potential source **73** in cooperation with diode **74** removes charge when the voltage of capacitor **75** (when going through its minimum capacitance) is greater than the potential of **73**. By having potential sources **70** and **73** adjustable and controllable by conventional voltage monitor **76**, the correct value of trapped charge for the system is maintained for desired voltage (or power) for load **77**. The regulating system shown in FIG. **18** may also be used to compensate for leakage losses.

FIG. **19** illustrates in block schematic form the advantages of the disclosed invention in supplying a high potential to a load such as a laser. In the conventional prior art systems, shaft power **90** turns conventional electrical generator **91** generating relatively low voltage, high current energy, to operate conventional high voltage power supply **92** which changes capacitor **93** through resistor **94**. Capacitor **93** discharges when switch **95** is closed to supply the load **96** with energy. In the present invention, shaft power **90*a*** directly actuates inversely ganged capacitors **93*a*** and **93*b*** providing an electrostatic energy charge equivalent to that placed on capacitor **93** by power supply **92**. Thus, the closing of switch **95*a*** provides the same energy to the identical load **96*a*** as in the prior art system. In the illustration bipolar pulses flow to load **96*a***. If unipolar pulses are desired for the load **96*a*** as for load **96** in the prior art circuit, conventional rectification of the bipolar pulse may be used.

I claim:

1. An alternating current electrostatic energy converter comprising:

a. a first and a second variable capacitor, each having a maximum and a minimum capacitance, connected in paired opposition and inversely ganged such that one capacitor passes through a maximum capacitance as the other capacitor is going through a minimum capacitance;

b. means for placing an initial and contained electrical charge on the said first and second capacitors;

c. means for actuating the said capacitors through their maximum and minimum capacitance passing contained charge between them; and

d. means for extracting power from the said capacitors.

2. An electrostatic alternating current generating system comprising:

a. a first and a second variable capacitor, each having a maximum and a minimum capacitance, inversely ganged on a common shaft such that one capacitor passes through a maximum capacitance as the other capacitor is going through a minimum capacitance;

b. means for placing an initial and contained electrical charge on the said first and second capacitors;

c. means for actuating the said shaft moving capacitors through their maximum and minimum capacitance;

d. an electrical load; and

e. means for connecting the said first and second variable capacitors in paired opposition to one another across the said load whereby contained charge is passed back and forth between the said capacitors through the said load.

3. An electrostatic alternating current generator comprising:

a. a first variable capacitor having a fixed plate and a movable plate providing a maximum and a minimum capacitance between the said fixed plate and the said movable plate;

b. a second variable capacitor having a fixed plate and a movable plate providing a maximum and a minimum capacitance between the said fixed plate and the said movable plate;

c. means for mechanically coupling the said movable plate of the said first capacitor to the movable plate of the said second capacitor such that the capacity of one variable capacitor is at a maximum capacitance when the other variable capacitor is at a minimum;

d. means for electrically connecting the said movable plates;

e. means for placing a contained electrical charge on the said variable capacitors such that the said fixed plates have like polarity charge;

f. means for actuating the said variable capacitors through a change of capacitance; and

g. means for connecting an electrical load between the said fixed plates of the variable capacitors, whereby with change of capacitance of the said capacitors, contained charge is passed between the said capacitors through the said load.

4. The apparatus as claimed in claim 3 wherein the said means for placing a charge on the said variable capacitors includes means for placing equal initial charges on the said variable capacitors.

5. The apparatus as claimed in claim 4 wherein a means for providing an evacuated enclosure and a means for positioning the said first and second variable capacitors within the said evacuated enclosure are provided.

6. The apparatus as claimed in claim 5 wherein the said means for actuating the said variable capacitors is rotational.

7. The apparatus as claimed in claim 5 wherein the said means for actuating the said variable capacitors is reciprocating.

8. A synchronous alternating current electrostatic motor comprising:

a. a first and a second variable capacitor each having a maximum and a minimum capacitance, connected in paired opposition inversely ganged on a common shaft such that one capacitor passes through a maximum capacitance as the other capacitor is going through a minimum capacitance;

b. means for placing an initial, contained, electrical charge on the said first and second capacitors;

c. means for placing an alternating potential voltage on the said first and second capacitors; and

d. means for connecting a mechanical load to the said shaft.

[57] **ABSTRACT**

An electrostatic charge generator for continually providing charge carriers of a given polarity in a flow of dielectric fluid. The charge generator comprises a coaxial tube with an inner conductor wire coaxial with a hollow, cylindrical outer conductor. A D.C. potential is applied between the inner and outer conductors of the coaxial tube and a dielectric liquid, such as oil, is caused to flow therethrough. Since the intensity of the non-uniform electric field in the conductor tube is highest near the inner conductor, the electrostatic charges of the opposite polarity as the inner conductor are removed from the dielectric fluid faster than charges of the same polarity are removed at the outer conductor. This results in the dielectric fluid exiting the conductor tube carrying a charge of the remaining polarity.

ELECTROSTATIC CHARGE GENERATOR

CROSS REFERENCE TO A RELATED APPLICATION

This application is related to patent application Ser. No. 812,883 filed July 5, 1977, now U.S. Pat. No. 4,123,697.

BACKGROUND OF THE INVENTION

The present invention relates to the field of electrostatic charge generators and more particularly to electrostatic charge generators for providing electrostatic charge carriers of a given polarity in a dielectric fluid. In even greater particularity, the present invention relates to such electrostatic charge generators for use in electrostatic high potential devices.

High potential devices capable of providing voltages in the tens-of-kilovolts range are widely used in the testing of insulation for electric machinery and cables. Standard high potential tests currently used include the AC high potential test and the DC high potential test.

AC testing is essentially a go/no-go test. The voltage is raised to a specified value and held for a specified length of time. The insulation is considered good if it can withstand the voltage without actually flashing over or breaking down or if the leakage current is not excessive. The current supply requirements in AC testing are quite high, and AC test sets tend to be very large. Since equivalent DC test sets are significantly smaller, DC high potential tests are widely employed to test insulation operation in an alternating current environment.

A standard DC high potential test is the leakage current versus voltage test. In this test, a voltage is applied across the insulation and raised in incremental steps up to and somewhat above the operating voltage. The steady state value of leakage current (after high initial capacitance and absorption currents) is noted at each step of voltage; as the test progresses, a curve of leakage current versus test voltage is determined. As long as this curve is relatively flat (equal increments of voltage giving equal increments of current), the item under test is considered to be in good condition. If the voltage is raised high enough, at some point, the current will start rising at a more rapid rate, appearing as a "knee" on the leakage current versus voltage curve. If the test is carried on beyond this point, the current increases at a much more rapid rate and breakdown soon occurs. Generally, the test procedure is to stop the voltage increments at this point, extrapolating the curve to estimate the breakdown voltage.

The DC high potential test, while versatile and widely used, has a number of disadvantages. The test set is still bulky and relatively immobile. In addition, for some types of insulation the knee occurs so close to the breakdown voltage that breakdown cannot be avoided. In this case, the DC high potential test exhibits the go/no-go characteristic of AC high potential testing which is undesirable in certain situations. This breakdown problem is a result of the current levels in present DC high potential test procedures, which, although in the milliamp range, result in large power dissipation requirements at tens-of-kilovolts.

The above limitations attendant to present DC high potential testing devices evidences a need for a high

potential test device capable of providing the required voltage level at significantly lower current levels.

One such high potential test device is an electrostatic high potential system as disclosed in our copending patent application Ser. No. 812,883 filed July 5, 1977, now U.S. Pat. No. 4,123,697. The system includes a dielectric fluid circulating through an electrostatic charge generator comprised of a dome shaped ionizing chamber enclosing a series of spiral chambers and baffles. This electrostatic charge generator causes a circulating dielectric liquid (oil) to carry an electrostatic charge of a given polarity, making use of the excellent electrostatic charge carrying (insulating) properties of these fluids. These charges are removed from the dielectric fluid in an electrostatic charge collection apparatus which steadily accumulates electrostatic charge to obtain the extremely high (tens of kilovolts) potentials associated with DC high potential test equipment. The disclosed electrostatic high potential system has the capacity to generate these high potentials with a relatively small amount of charge (corresponding to the microamp range).

SUMMARY OF THE INVENTION

In the above context, the present invention is directed to an improved electrostatic charge generator capable of generating electrostatic charge carriers of a given one of either polarity in a circulating dielectric fluid.

Accordingly, the present invention provides an electrostatic charge generator which utilizes the phenomenon of electrostatic charge generation in a dielectric fluid flow. The electrostatic charge generator comprises a coaxial tube with an inner length of conductor wire coaxial with a hollow cylindrical outer conductor. A voltage supply provides a potential difference between the inner and outer conductor of the charge generator, and a dielectric fluid is circulated therethrough.

Since the intensity of the non-uniform electric field in the coaxial charge generator is highest near the inner conductor, electrostatic charges of the opposite polarity of this inner conductor are removed from the dielectric fluid more rapidly than the complementary charges are removed at the outer conductor. Thus, the dielectric fluid exiting the charge generator carries an amount of charge of the remaining polarity.

The novel features believed to be characteristic of the present invention are set forth in particularity in the appended claims. However, a more complete appreciation of the present invention, both as to organization and mode of operation, and many of the attendant advantages thereof will result as the same becomes better understood by reference to the following detailed description when considered in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a cross-section, isometric view of a portion of the coaxial charge generator according to the present invention showing the inner and outer conductors.

FIG. 2 is a schematic diagram showing an electrostatic high potential device incorporating the electrostatic charge generator.

FIG. 3 is a longitudinal cross-section of the coaxial charge generator illustrating the charge generation mechanisms which provide the electrostatic charge carriers.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Electrostatic charges are generated in a dielectric fluid whenever the fluid comes in contact with another material. As used in the discussion herein, dielectric fluid refers to a liquid such as oil or a mixture of oil and water as hereinafter described. The generation and accumulation of electrostatic charges are dependent upon certain properties of the dielectric fluid, such as electrical conductivity and electrostatic charging tendency, as well as system design and fluid flow conditions. With the improved filtering and refining today, present dielectric fluids exhibit greater electrical resistance (lower conductivity) inhibiting charge recombination and thus allowing greater charge accumulation. This is to be contrasted with fluids such as water which generate considerable electrostatic charges which, due to high conductivity, recombine very quickly, precluding the charge accumulation.

The principal mechanism responsible for the electrostatic charge generation phenomenon in a dielectric fluid is the electric "double layer" at the boundary between a solid and a liquid or between two different liquids. (It is a misconception that the charges in a dielectric fluid are generated by the friction between the moving fluid and a conduit wall.) In the hydrocarbon fluid (oil), some impurities or foreign matters are dissolved as positive and negative charged ions. As a result of the absorption of ions of one polarity on the surface of the conduit carrying the flow, the dielectric fluid generally carries ions with the opposite charge to those on the conduit surface. An electric double layer is thus formed at the interface between the fluid and the solid conduit surface. The electrostatic charges remaining in the liquid are carried by the flow of the dielectric fluid resulting in a flow of electricity known as the streaming current. Continuous flow of the dielectric fluid can accumulate enough electrostatic charge to provide high potential levels (voltages in excess of 24 Kv have been observed in fueling operations).

The electrostatic charging tendency of a fluid varies from fluid to fluid but is greatly affected by the presence of impurities. For instance, it has been noted that a two-phase mixture (such as oil and water) is a very good electrostatic charge generator, with the types of impurities permitting higher charge generation appearing to be those that increase the charging tendency of the fluid without significantly affecting its electrical conductivity. As the conductivity of the two-phase mixture reaches a certain level, the electric double layer is destroyed (due to the rapid recombination of charges) and the charge generation effect ceases.

Referring now to the drawings wherein like reference characters designate like or corresponding elements throughout the several views, FIG. **2** shows in schematic form an electrostatic charge generator **10** according to the present invention incorporated in an electrostatic high potential system **15**. The electrostatic high potential system additionally comprises a pump **20** and an electrostatic charge collector **20**. An electrostatic high potential system similar to that indicated at **15** is the subject of the above referenced copending application. As noted above, electrostatic charge generation therein is accomplished by means of a dome shaped ionizing shell enclosing a system of baffles and spiral passageways. Electrostatic charge generator **10** is an improved device for generating electrostatic charges of a given polarity in a circulating dielectric fluid, for example, oil or a mixture of oil and distilled water.

Referring to FIG. **1**, electrostatic charge generator **10** comprises a coaxial conductor having an inner conductor wire **12** coaxial with a hollow, cylindrical outer conductor **13**. A voltage supply **24** applies a potential V_g between outer conductor **13** and inner conductor **12** (inner conductor **12** being indicated to be at a negative potential).

Referring again to FIG. **1** and electrostatic high potential device **15**, pump **20** causes a dielectric fluid to flow, via a conduit **22**, through coaxial charge generation tub **10** at a predetermined rate (as explained below, this rate of flow should at a minimum be sufficient to cause the dielectric fluid to turbulently flow through the charge generator). As discussed below, the dielectric fluid exiting charge generation tube **10** carries a negative electrostatic charge. The negatively charged dielectric fluid flows through a conduit **25** into charge collection apparatus **30** via an inlet port **32**. The dielectric fluid in charge collection apparatus **30** then flows back to pump **20** via an outlet port **34** and a conduit **26** to be recirculated.

Charge collection apparatus **30**, as disclosed in the above referenced copending patent application, comprises an electrically conductive dome shaped shell enclosing spiral passageways and tree electrodes. The points of the tree electrodes intensify the electric field and act to discharge the negative electrostatic charge carried by the dielectric fluid, i.e., draw off the negative charges and accumulate them along the equipotential surface of the conductive shell of charge collection apparatus **30**. In this manner, the large (tens-of-kilovolts) potentials associated with high potential devices can be accumulated on charge collection apparatus **30**.

The electrostatic charge generation process embodied in coaxial charge generator **10** actually comprises two separate mechanisms: the electric double layer effect, described above with respect to ionized impurities in dielectric fluid flow, and a dielectrophoresis effect arising from the non-uniform electric field within the charge generator. As discussed above, a certain degree of electrostatic charge generation (the streaming current) occurs whenever a dielectric fluid flows through a solid tube, as a result of the transfer of charge from ionized impurities of a given polarity to the tube. This electric double layer effect is enhanced in the present invention by reason of the applied potential difference V_g between inner conductor **12** and outer conductor **13** of coaxial charge generator **10**. Ionized impurities in the dielectric fluid are drawn toward the complementarily charged conductor. However, since the intensity of the non-uniform electric field is highest near inner conductor **12** (which is at a negative potential with respect to outer conductor **13**), positive charges are drawn out of the dielectric fluid relatively more rapidly than are negative charges. This results in a gradual accumulation of negative charge carriers as the dielectric fluid flows through coaxial charge generator **10**.

Further enhancing the electric double layer mechanism is the ionizing effect on the electrically neutral hydrocarbon molecules of the dielectric fluid within coaxial charge generator **10**. As best explained with reference to FIG. **3**, electrically neutral hydrocarbon molecules contacting the relatively large surface area of outer conductor **13** (A) tend to be positively ionized through the loss of negative charge to the positively charged outer conductor. These positively charged ions than behave in the same manner as positively ionized impurities, migrating under the influence of the non-uniform electric field toward inner conductor **12** (B). As in the case of ionized impurities, the negatively charged inner conductor **12** draws off positive charge leaving a negatively charged hydrocarbon molecule (C). And, if the dielectric fluid flows through coaxial charge generation tube **10** at a rate sufficient to produce turbulence within the tube, the turbulent flow adjacent to outer conductor **13** (indicated by the curved arrows in FIG. **3**) continuously sweeps ionized hydrocarbon molecules away from the outer conductor toward inner conductor **12**, enhancing the flow of positively charged ions toward this inner conductor. Thus the importance of circulating the dielectric fluid through charge generator **10** at a rate sufficient to insure a turbulent flow.

The second charge generation mechanism results from the "dielectroporesis" effect of a non-uniform electric field on an electrically neutral molecule. As best explained with reference to FIG. **3**, electrically neutral hydrocarbon molecules become polarized in the non-uniform electric field which exists between outer conductor **13** and inner conductor **12** of coaxial charge generator **10** (X). This polarization effect of the electric field within charge generator **10** can be seen as producing induced electric dipoles of the electrically neutral hydrocarbon molecules within the dielectric fluid. The non-uniform electric field causes a measure of corresponding alignment of these induced dipoles. Because the field is non-uniform, one end of the dipole is in a weaker field than the other. Thus, a net force results and the hydrocarbon dipole is pulled towards the area of greatest field intensity, i.e., the area of inner conductor **12** (Y). As these electric dipoles are drawn into contact with the negative polarity of inner conductor **12**, positive charges are removed from the molecules resulting in additional negative charge carriers (Z).

The above described electrostatic charge generation mechanisms combine to produce an abundance of negative charge carriers in the dielectric fluid as the fluid traverses coaxial charge generator **10**. Also, it is apparent that if the polarity of V_g (and, consequently, of the inner conductor of electrostatic charge generator **10**) is reversed, the dielectric fluid would carry a predominance of positive rather than negative charges. Thus, the polarity of the accumulated electrostatic potential on electrostatic charge collection apparatus **30** can be controlled.

In a preferred embodiment of the electrostatic charge generator according to the present invention, coaxial charge generator tube **10** is approximately three feet long and comprised of a one-half inch diameter copper tube as outer conductor **13**, and an uninsulated copper wire as inner conductor **12**. When this electrostatic charge generator is disposed in electrostatic high potential device **15** and a two-phase dielectric fluid mixture (a liquid consisting of ten parts transformer oil to one part distilled water) is caused to circulate therethrough at a rate of approximately three gallons per minute, electrostatic potentials in the neighborhood of 50 kilovolts can be obtained for a value of V_g of forty volts DC. (For most high potential testing, a DC voltage of 30 kilovolts is sufficient.)

The value of V_g can be increased to obtain a more rapid generation of charge carriers and a correspondingly more rapid electrostatic potential build-up in electrostatic charge collection apparatus **30**. However, increases in V_g beyond a certain point (depending upon the type of oil and the type and amount of additives) results in an abrupt cessation of generated voltage, due to the breakdown of the oil causing an increase in conductivity of the dielectric fluid. This prevents any substantial charge from building up.

Obviously, other embodiments and modifications of the present invention will readily come to those of ordinary skill in the art having the benefit of the teachings presented in the foregoing description and the drawings. It is therefore to be understood that this invention is not to be limited thereto and that said modifications and embodiments are intended to be included within the scope of the appended claims.

What is claimed is:

1. An electrostatic charge generator for continuously providing charge carriers of a given polarity in a flow of dielectric liquid, comprising:

a. a coaxial tube comprising:
  1. an inner conductor wire; and
  2. a hollow, cylindrical outer conductor coaxial with said inner conductor;

b. voltage means for applying a DC potential between said inner and said outer conductor; said DC potential creating a non-uniform field the intensity of which is highest near said inner conductor;

c. a circulating dielectric liquid;

d. flow means for causing said dielectric liquid to continuously circulate through said coaxial tube at a rate to insure a turbulent flow;

e. said dielectric liquid being depleted of charges of the opposite polarity of said inner conductor more rapidly then complementary charges are removed at the outer conductor as the dielectric liquid is caused to flow through said coaxial tube, such that the dielectric liquid exiting said coaxial tube carries charges of the complementary polarity;

f. the polarity of said voltage means operable to be reversed for changing the polarity of the charges carried by said dielectric liquid and thus control the polarity of the accumulated charges; and

g. said dielectric liquid comprising a two-phase mixture consisting of from 90 to 100 percent oil and from 0 to 10 percent distilled water.

2. The electrostatic charge generator as recited in claim **1** wherein said dielectric liquid comprises 100 percent oil and 0 percent distilled water.

3. The electrostatic charge generator as recited in claim **2** wherein said coaxial tube comprises:

a. an inner conductor of uninsulated copper wire; and

b. an outer, cylindrical conductor of copper tubing.

4. An electrostatic charge generator as in claim **1** wherein the oil component of said dielectric liquid is transformer oil.

5. In an electrostatic high potential system which includes an electrostatic charge generation chamber and an electrostatic charge accumulation chamber together with means for continuously circulating a dielectric liquid therethrough, an improved electrostatic charge generation chamber comprising:

a. a coaxial tube comprising:
  1. an inner conductor wire;
  2. a hollow, cylindrical outer conductor coaxial with said inner conductor; and

b. voltage means for applying a DC potential between said inner and said outer conductor; said DC potential creating a non-uniform field the intensity of which is highest near said inner conductor;

c. said dielectric liquid being circulated through said coaxial tube at a rate to insure a turbulent flow and being depleted of charges of the opposite polarity of said inner conductor more rapidly than complementary charges are removed at the outer conductor such that the dielectric liquid exiting the coaxial tube carries electrostatic charges of the complementary polarity; and

d. the polarity of said voltage means operable to be reversed for changing the polarity of the charges carried by said dielectric liquid and thus control the polarity of the accumulated charges.

6. The electrostatic charge generator as recited in claim **5** wherein said coaxial tube comprises:

a. an inner conductor of uninsulated copper wire; and

b. an outer, cylindrical conductor of copper tubing.

7. The electrostatic charge generator as recited in claim **6** wherein said coaxial tube is approximately three feet in length and one-half inch in diameter.

8. The electrostatic charge generator as recited in claim **6** wherein said voltage means supplies a DC voltage of approximately 40 volts.

9. An electrostatic charge generator as in claim **6** wherein said dielectric liquid comprises a two-phase mixture consisting of from 90 to 100 percent oil and from 0 to 10 percent distilled water.

10. An electrostatic charge generator as in claim **9** wherein said oil is transformer oil.

UNITED STATES PATENT OFFICE.

FRANCESCO GHILARDUCCI, OF ROME, ITALY.

ELECTROSTATIC MACHINE.

1,011,939. Specification of Letters Patent. Patented Dec. 19, 1911.

Application filed July 2, 1908. Serial No. 441,697.

To all whom it may concern:

Be it known that I, FRANCESCO GHILARDUCCI, a subject of the King of Italy, residing at Rome, Italy, professor at the Roman University, have invented certain new and useful Improvements in Electrostatic Machines, of which the following is a specification.

My invention relates to electrostatic machines, as they are used for producing Röntgen rays, for space telegraphy and in electro-therapeutics, and has for its object to make certain improvements in electrostatic machines of a well-known type, such as the Holtz machine.

My invention more particularly consists in making the stationary disk in two parts, supported by the insulating casing, and provided with flanges at their opposite straight edges, and mounting the rotatable disk on a shaft, supported independently of the casing upon a wall or other rigid structure. The most important advantage obtained by this improvement is the prompt and certain self-excitability of the machine under any atmospheric conditions, and in addition an enormously superior output is obtained from my machine as compared with other machines of equal dimensions, because the rotatable disk can be operated at an extraordinarily high speed, whereas the support for the stationary disk can be made of glass, which is a good insulating material. On account of the gap between the two parts of the stationary disk and on account of the flanges provided at their opposed straight edges, a most perfect insulation of the two parts of the stationary disk is effected. My machine, moreover, works perfectly even in a humid atmosphere and is therefore always ready to perform any radio-telegraphic and electro-therapeutic operations.

In the accompanying drawing, Figure 1 is a front view of an electrostatic machine of the well-known Holtz type with my new improvements; Fig. 2 is a side view of the machine as shown in Fig. 1; Fig. 3 a perspective view of a section of the stationary disk.

1 designates the rotatable disk, which is made of hard rubber, or glass, or the like, and is mounted on a shaft 4, which shaft has no support at its front end, but is journaled in a bearing provided in a socket of a wall or other rigid body, so that a very rapid rotation of about 3,000 revolutions per minute may be given to the disk without setting up oscillation therein. By thus journaling the shaft 4, carrying the rotatable disk 1 in a bearing independent of the casing, the bottom plate of the latter may be made of glass, since it is not subjected to any strains, which would occur, if the shaft 4 were journaled in the casing. This arrangement results, at the same time, in a great gain in insulation. The casing is therefore made entirely of glass, and the sections 2 and 3 of the stationary disk are supported each from the top 5 and the bottom plate 6 of the casing, so as to leave a gap of at least one centimeter between their straight edges, as clearly shown in Fig. 1. In the center of their straight edges, the sections 2 and 3 are recessed, so as to form a circular opening, through which the shaft 4 supporting the disk 1 passes. The sections 2 and 3 of the stationary disk are also made of hard rubber, or preferably of glass, and are each provided at their straight edges with an upright flange 7 at right angles to the planes of the sections and preferably about eight centimeters high. The distance between the two flanges is about 1 centimeter. Each section is provided with a tinfoil armature 8, which is covered with paraffin paper 9. The armatures 8 are connected with the brush-carriers 10 and 11, which are adapted to slide on the front face of the disk 1, while the latter rotates. By a metal rod 14 there is connected to each brush-carrier a small capacity 12 and 13 respectively. By the arrangement of these capacities, the inductive effect of the machine is increased and a corresponding potential increase is effected. The capacities are preferably so located that their rims are about three centimeters away from the collecting combs 15. The collecting combs 15 are supported from the top 5 of the casing and terminate in small knobs 26, which are adjustable by means of brass-rods provided with ebonite handles, so that the knobs 26 can be moved nearer to and farther away from other knobs 27, whereby a variable spark gap may be formed. The two sections of the stationary disk can be brought into contact with the ground by means of two metal rods 22, adapted to slide in insulating tubes 23, secured to the under side of the bottom plate 6 of the casing. Contact is made between the said metal rods and

the armature by the pulling of a cord 25, whereby the armatures of the two sections of the stationary disk are discharged, and the polarity of the machine is reversed. Thus the polarity of the machine may be changed even at a distance. The grounding of the discharges is effected by means of metal chains 24, which, as shown in Fig. 1, are connected to the metal rods 22.

As seen from Figs. 1 and 2, a neutralizing rod is provided, provided at each of its metallic terminals 16 with three brushes. The said terminals are connected by a bent wire 17, which is bow-shaped and fixed at its center to a metal rod 18, adapted to slide in an insulating tube 19, secured to the front plate of the casing. By means of a handle 21 attached to the rod 18, the latter can be turned to give a right or left hand inclination to the neutralizing rod, the effect of this being to vary the tension, or to reverse the polarity of the machine. The polarity is reversed by giving the neutralizing rod a maximum right hand inclination and then returning it to its normal position, shown in Fig. 1. By moving the neutralizing rod nearer to the disk 1, or farther away therefrom, also the electric tension of the machine can be varied.

By making the stationary disk of two sections, as described and shown, and providing a neutralizing rod, the machine can be easily and promptly deënergized by giving the neutralizing rod a turn to move it from its normal position shown in Fig. 1 into a position in which it will lie above the gap formed between the straight edges of the two sections 2 and 3. The deënergizing of the machine can also be obtained by establishing a metallic connection between the two armatures 8 of the sections 2 and 3 of the stationary disk. As soon as the neutralizing rod is returned to its normal position, or after the metallic connection between the armatures has been interrupted, the machine immediately becomes again energized.

In conjunction with the knobs 26 above referred to, two condensers 28 of adjustable capacity may be provided to increase the strength of the electric discharges.

I claim:

1. In an electrostatic machine of the Holtz or a similar type, the combination with an insulating casing of a rotatable ebonite disk supported independently of the said casing, a stationary disk made of insulating material, and comprising two independent sections, forming a gap between them and supported each by the top and bottom of said casing, an armature on each of said sections and brushes connected to said armature and adapted to slide on the front faces of said rotatable disk.

2. In an electrostatic machine the combination with an insulating casing, a rotatable shaft journaled independently of said casing, an ebonite disk mounted on said shaft, a stationary disk made of insulating material, and comprising two sections, forming a gap between them and supported each by the top and bottom of the said casing, an armature provided on each section, brushes connected to said armatures and adapted to slide on the front face of said disk during its rotation, collecting conductors, a neutralizing rod, a plurality of brushes carried at its terminals, an insulating tube carried by the front plate of the casing, a rod carrying said neutralizing rod and capable of adjustment in said insulating tube, an operating handle for moving said metal rod in said tube both longitudinally and axially.

3. In an electrostatic machine the combination with an insulating casing, a rotatable shaft journaled independently of said casing, an ebonite disk mounted on said shaft, a stationary disk made of insulating material, and comprising two sections, forming a gap between them and supported each by to the top and bottom of the said casing, an armature provided on each section, brushes connected to said armatures and adapted to slide on the front face of said disk during its rotation, collecting conductors, a neutralizing rod, a plurality of brushes carried at its terminals, an insulating tube carried by the front plate of the casing, a rod carrying said neutralizing rod and capable of adjustment in said insulating tube, an operating handle for moving said metal rod in said tube both longitudinally and axially, and insulating tubes attached to the bottom of the casing, and metal rods adapted to slide in said insulating tubes and to connect the armatures of the two sections of the said stationary disk.

In testimony whereof I have affixed my signature in presence of two witnesses.

FRANCESCO GHILARDUCCI.

ABSTRACT: A device for collecting a charge of static electricity by rotating a disc or wheel carrying a plurality of individual conductors in proximity to a pair of stationary conductors. Four stationary brushes are arranged in two pairs to wipe the charge from the individual conductors which is initially induced by the natural imbalance in static charge between the stationary and moving conductors. The charges from each pair of brushes are returned to the stationary conductors and stored on an appropriate capacitor.

ELECTROSTATIC GENERATOR

This invention relates to electrostatic generators or static electric machines.

Although static electricity has relatively few practical uses, as compared to current electricity, a large number of mechanical arrangements have been devised for concentrating electrical charges produced by attraction and repulsion between particles carrying like or unlike electrical charges. Certain types of electrostatic generators have been successfully used to boost protons and other nuclear particles to energy levels of 10 million electron volts, producing narrow beams of known energy which may be used to study nuclear forces. Other such devices are intended to accumulate much lower charges and may be used merely as instructional aids in demonstrating the physical phenomena which they represent.

The present invention comprises an electrostatic generator of the rotary type wherein electrons are moved through brushes from moving conductors to stationary conductors to cause an initial, low imbalance in electrical charge to become greater and greater. The brushes are preferably provided at intervals of 90° around the path of the rotating conductors, the brushes of one opposing pair being electrically connected to one another and the other pair being insulated from one another and individually connected to the two stationary conductors. The latter may conveniently be carried on a rigid backing which also supports the rotatable disc with the movable conductors in a closely spaced, parallel plane. The backing plate and disc may be carried by a base support which also holds the plates of a capacitor which stores the charge conducted from the stationary conductors. The brushes may be positioned between the backing plate and rotatable disc, or may be (preferably in smaller dimensioned units) carried by arms attached to the backing plate and extending on the opposite side therefrom of the disc.

It is a principal object of the invention to provide an electrostatic generator adapted to accumulate an electrical charge of relatively high voltage in relation to its size.

A further object is to provide a simple and economical device of instructional value in demonstrating the phenomenon of static electricity and accumulation of high-voltage charges therefrom.

Still another object is to provide a device extremely inexpensive to fabricate and assemble which will cyclically charge a capacitor and allow discharge or arcing thereof each time the charge reaches a predetermined voltage level.

Other objects of the invention will in part be obvious and will in part appear hereinafter.

The invention accordingly comprises the features of construction, combination of elements, and arrangement of parts, which will be exemplified in the construction hereinafter set forth, and the scope of the invention will be indicated in the claims.

For a fuller understanding of the nature and objects of the invention reference should be had to the following detailed description taken in connection with the accompanying drawings, in which:

FIG. 1 is a front perspective view of one embodiment of apparatus embodying the invention;

FIG. 2 is a rear elevational view of the apparatus of FIG. 1;

FIG. 3 is a side view in section on the line 3—3 of FIG. 2;

FIG. 4 is a front perspective view of a second embodiment of the invention;

FIG. 5 is a rear view of the FIG. 4 embodiment; and

FIG. 6 is a side view in section on the line 6—6 of FIG. 5.

The invention is shown in a first embodiment in FIGS. 1–3 comprising base 10, adapted to rest on a flat surface and support the other elements, backing plate 12, attached to base 10 by brackets 14, and disc 16 rotatably supported with respect to the backing plate. Disc 16 is made of material which is a good electrical insulator and carries a plurality of individual electric conductors 18, each insulated from the others. A first pair of brushes 20 and 22 is carried by arm 24, which is made of electrically conducting material at least in the portion between brushes 20 and 22 so that the latter are in electrical contact with one another.

Arm 24 is attached to backing plate 12 by screws, rivets or other appropriate fasteners and insulated therefrom by spacers 26 and 28 which hold the arm in slightly spaced relation to the front surface of disc 16. A second pair of brushes 30 and 32 is held by conducting arms 34 and 36, respectively, which are attached to backing plate 12 by conducting screws 38 and 40 and held in properly spaced relation by spacers 42 and 44. Arms 34 and 36 may be joined, of course, to form a single arm, crossing arm 24, if the portion between brushes 30 and 32 is made of an insulator so that the brushes are not in electrical contact with one another.

Turning now to FIG. 2, backing plate 12 carries on its rear surface a pair of stationary conductors designated generally by the reference numerals 46 and 48. Conductor 46 includes a pair of lobes 50 and 52, spaced at 90° on the path of a circle rearwardly adjacent conductors 18 on disc 16, and joined by conducting path 54. Lower conducting portion 56 is joined by path 58 to lobe 52. Conductor 48 includes lobes 60 and 62, also spaced 90° from one another and from lobes 50 and 52, electrically connected by conducting path 64 and connected to lower portion 66 by conducting path 68. Lower portions 56 and 66 of the stationary conductors are connected to opposite plates of an appropriate capacitor, shown schematically in FIG. 2 and indicated by the reference numerals 76 and 78.

Also carried on the rear surface of backing plate 12 is electric motor 70 having cord 72 for connection to an appropriate power source for driving the motor. Shaft 74 (FIG. 3) of motor 70 extends through an opening somewhat larger than the shaft in backing plate 12 and disc 16 is mounted on the end of the shaft with rubber grommet 75 providing a tight frictional engagement.

The space between adjacent surfaces of backing plate 12 and disc 16 should be minimal since the initial flow of electrons from conductors 18 through the brushes upon movement of disc 16 is induced by the natural imbalance in charge between the stationary conductors on the backing plate and the adjacent movable conductors on the disc. For example, lobe 62 of stationary conductor 48 will naturally have an initial concentration of electrons either higher or lower than that of the adjacent conductor 18, shown in the uppermost position in FIG. 3 and designated with the notation 18′. Assuming lobe 62 is more negative it will tend to repel any negative charge in conductor 18′, driving electrons through conducting brush 20. The loss of electrons results in conductor 18′ becoming positively charged as electrons flow through brush 20, conducting support arm 24 and brush 22 to collect on the movable conductor shown in the lowermost position in FIG. 3 and designated with the notation 18″. Thus, conductors 18′ and 18″ carry positive and negative charges, respectively, as they move in a clockwise direction out of contact with brushes 20 and 22. When these two conductors reach brushes 32 and 30, respectively, the charges are wiped off, the positive charge from conductor 18′ flowing through brush 32, conducting arm 36, conducting screw 40 and is transferred to stationary conductor 46. The negative charge from conductor 18″ flows through brush 30, conducting arm 34, conducting screw 38 and is transferred to stationary conductor 48. These two movable conductors (18′ and 18″) are then neutral until returning to their respective original positions at the top and bottom of disc 16 as shown in FIG. 3 and the process is repeated. The same cycle applies, of course, with all the movable conductors as the disc continues to rotate and the positive and negative charges transferred to stationary conductors 46 and 48, and thus to capacitor plates 76 and 78, respectively, continue to increase.

Turning now to the embodiment of FIGS. 4–6, wherein like reference numerals are used to denote elements which may be the same as those shown in the first embodiment, base 10 again supports backing plate 12, attached thereto by brackets 14. Disc 16 carries a plurality of radially spaced and individually insulated conductors 18, this time facing backing plate **12**. Disc **16** is centrally supported on shaft **74** of motor **70**, with rubber grommet **75** providing a tight frictional engagement. Again stationary conductor **46**, having lobes **50** and **52** and conducting paths **54** and **58**, and conductor **48**, having lobes **60** and **62** and conducting paths **64** and **68**, are provided on the side of backing plate **12** opposite disc **16**.

In the present embodiment, however, the arms supporting the brushes are omitted since the latter are mounted directly on the backing plate. Brushes **30** and **32** are connected to stationary conductors **46** and **48**; brushes **20** and **22** are again in electrical contact with one another, but in the present embodiment this is accomplished by an additional conducting path **80** on backing plate **12**, as seen in FIG. **5**. Thus, the basic operation of the apparatus to cause steadily increasing positive and negative charges on stationary conductors **46** and **48** as disc **16** is rotated is the same as in the first embodiment. The structure is somewhat simplified, however, by elimination of the brush support arms. The linear distance between the closest points on conducting path **80** and stationary conductors **46** and **48** must, of course, be great enough that arcing does not occur as the electrostatic charge builds up.

Also shown in the FIGS. **4–6** embodiment is a means for incorporating the capacitor plates directly in base **10**. Brackets **14** are made of a conducting material and attached directly to stationary conductors **46** and **48**. The bracket attached to stationary conductor **48** rests on plate **78**, which is exposed on a portion of the upper surface of base **10**, being secured thereto by screw **82**. The bracket attached to stationary conductor **46** is secured to base **10** by conducting screw **84**, which passes through insulating layer **86**, plate **76** and into insulating layer **88**. Thus, conductor **46** is placed in electrical contact with capacitor plate **76** by the bracket and screw **84**. In this embodiment base **10** may most conveniently be made of two pieces, namely, insulating sheets **86** and **88** having conducting plates **78** and **76**, respectively, integral therewith. Also, it may be desirable to have a portion of the upper surface of plate **76** exposed, by cutting away some of insulating layer **86**, to facilitate shorting the capacitor plates as desired. The plates may be spaced in either embodiment, of course, so that arcing between the plates occurs each time the charge reaches a predetermined level.

Backing plate **12**, carrying stationary conductors **46** and **48**, and disc **16**, carrying movable conductors **18**, may be conveniently fabricated in the manner of circuit boards, i.e., by providing sheets of insulating material covered with a thin conducting layer of copper, or the like, and removing portions of the latter by etching to leave the desired conducting areas on the sheet. Brushes **20, 22, 30** and **32** may be economically and conveniently formed as loops of conducting tape, such as rubber tape containing carbon.

I claim:

1. An electrostatic generator comprising, in combination:

a. a first pair of conducting brushes electrically connected to one another;

b. A second pair of conducting brushes electrically insulated from one another and from the brushes of said first pair;

c. first and second electrical conductors mounted on a common first support and electrically insulated from one another,

d. means electrically connecting one of the brushes of said second pair to said first conductor, and the other to said second conductor;

e. a plurality of individually insulated additional conductors mounted on a common second support;

f. means for causing movement of said additional conductors relative to said brushes, in successive winding contact with brushes of opposite ones of said pairs, and to said first and second conductors, in physical proximity thereto close enough to allow significant mutual influence of the respective electrical charges of said additional conductors on said first and second conductors, but electrically insulated therefrom; and

g. means forming an electrical capacitor with the plates connected respectively to said first and second conductors.

2. The invention according to claim **1** wherein said additional conductors are arranged in a circular configuration and said relative movement is rotary.

3. The invention according to claim **2** wherein said additional conductors are arranged on an insulating disc which is rotated while said brushes and said first and second conductors remain stationary.

4. The invention according to claim **3** wherein said brushes and said first and second conductors are carried on an electrically insulating backing plate which also supports motive means for rotating said disc.

5. The invention according to claim **4** wherein said disc and said backing plate are arranged in closely adjacent, parallel planes and said first and second conductors are on the opposite side of said backing plate from said disc.

6. The invention according to claim **5** wherein said first pair of brushes are supported on said backing plate and electrically connected to one another by a further conductor arranged on said backing plate.

7. The invention according to claim **5** wherein said first pair of brushes are supported on and electrically connected to one another by an arm supported on said backing plate in spaced relation to said disc.

8. The invention according to claim **6** wherein said additional conductors are carried on the side of said disc which faces said backing plate and said brushes are spaced 180° from the other brush of the same pair and 90° from the brushes of the opposite pair.

9. The invention according to claim **8** wherein said first conductor includes two enlarged portions, electrically connected and spaced 90° from one another on the path of a circle in a plane adjacent the plane of rotation of said additional conductors, and said second conductor includes two enlarged portions, electrically connected and spaced 90° from one another and from the two portions of said first conductor on the path of said circle.

10. The invention according to claim **9** wherein said backing plate is supported on a base whereon the plates of said capacitor are arranged.

[57] **ABSTRACT**

Method and apparatus for electrostatically generating power by converting random mechanical motion into electrical energy. The apparatus includes two variable capacitors that have their capacitances varied in an alternating manner by the physical displacement of a common conductor that forms one plate in each of the capacitors. The variable capacitors are formed in a container which holds a fluid for increasing the output power of the apparatus. The fluid in combination with movable conductor also generates sufficient charge to bias the variable capacitors.

ELECTROSTATIC GENERATOR AND MOTOR

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention generally relates to electrical power-generating systems, and more particularly, to electrostatic generators.

2. Description of the Prior Art

In the past the need for replacing storage batteries has presented problems in convenience, planning and cost. These problems were especially important for the batteries used in portable electronic and electrical equipment. For example, the batteries used for electrical watches, portable radios, calculators, and hearing aids heretofore required frequent replacement. This replacement often was annoying to the owner because of the length of time the equipment was out of service and the high replacement cost of the batteries.

In the watch industry there has been a continuing search for a power source that can make electronic watches as maintenance free as self-winding watches. The industry has been looking for a system that will permit electronic watches to operate indefinitely.

Recently, there has developed a particular problem in the electronic watch industry. Digital watches have become fashionable and some are equipped with light emitting diodes. These diodes draw more current than conventional electronic watch circuits, and often the batteries in these watches require replacement every three or four months. At the present time none of the commercially available electronic watch circuits are equipped with a battery charging system, and the watch battery must be replaced each time the battery is discharged.

The present invention incorporates the well known physical principle that electrical energy can be generated from mechanical motion by mechanically alternating the capacitances of a plurality of capacitors. This principle, however, has never been successfully incorporated into battery charging systems and power generators because the output of these previous systems was too unsymmetrical. Although current was generated in these older systems, the systems could not be adapted to efficiently generate usable AC power.

Another problem encountered with prior electrostatic generators has been the electrical breakdown of the medium between the plates of the capacitors. These generators most efficiently generate power when operated at as high a voltage as possible. Heretofore the upper operating voltage limit was determined by the electrical breakdown of the medium between the plates. For example, if air surrounds the plates, then at high voltage, the electric field causes the air to ionize. The conductive ions thus produced deposit on the surface of the dielectric and make its surface electrically neutral. This type of electrical breakdown of the medium greatly reduces the efficiency of the system.

The present invention also makes use of the triboelectric effect as an alternative principle of operation. The triboelectric effect is the generation of electric charge as a result of the friction between two bodies. The bodies move with respect to each other and electric charge builds up. The moving bodies are fabricated from different materials and the amount of charge produced is proportional to the amount and the frequency of the frictional contact.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a novel method and apparatus that overcomes the limitations and disadvantages of the prior art.

A further object of the present invention is to convert random mechanical motion into electrical energy by utilizing both gravitational and acceleration forces.

An additional object of the present invention is to develop an electrical energy generator for use in applications where space is at a minimum. This objective includes developing a circuit that operates in the simplest possible manner, utilizes a minimum number of components, and contains the simplest possible circuit. One application of the present invention is for charging electronic watch batteries where space and weight are both limited.

Another object of the present invention is to increase the power-generating efficiency of an electrostatic generator by raising the capacitor breakdown voltage. This permits the generator to operate at a higher voltage and gives the capacitors higher field strength.

Still another object of the present invention is to utilize the triboelectric effect and to eliminate the need for a bias supply for the capacitors. The elimination of the bias supply in the present invention both simplifies the electrical circuit and reduces the cost of producing the apparatus.

These and other features are embodied in a method and apparatus for electrostatically generating power by converting random mechanical motion into electrical energy. The apparatus includes two variable capacitors formed in a container for holding a fluid. The capacitors share a common dielectric member and a common plate. Mechanical motion is used to inversely alternate the capacitance of the two capacitors. The container is filled with a fluid for reducing charge leakage and for increasing the electrical breakdown voltage of the capacitors. This fluid with properly selected properties in combination with the movable conductive plate also generates sufficient charge via the triboelectric effect to bias the two variable capacitors during operation.

A feature of the present invention is that the threshold voltage at which power generation is commenced is easily reached for any small, relative change in the values of capacitance of the variable capacitors. In addition, although the cycle of voltage oscillation and the amount of electrical charge transferred between the capacitors are both dependent on the amount of mechanical motion, these two quantities are completely independent of the rate at which the mechanical motion occurs. Although a slow rate of mechanical motion generates a lower current, power generation in the present invention never ceases as long as capacitor modulation exceeds a predetermined minimum value.

Additional objects and features of the invention will appear from the following description in which the preferred embodiment has been set forth in detail in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic diagram of one embodiment of the circuit of the present invention.

FIG. 2 is a perspective view, partially cut away, of a variable capacitance, electrical energy generator according to the present invention.

FIG. 3 is a side elevation, in section, of the electrical energy generator of FIG. 2.

FIG. **4** is a side elevation, in section and partially cut away, of the electrical energy generator of FIG. **2**, illustrating the triboelectric generation of charges.

FIG. **5** is a block diagram of one output for the circuit of FIG. **1**.

FIG. **6** is a schematic diagram of an alternative embodiment of the present invention illustrating the apparatus as an AC generator.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIG. **1** is a schematic diagram of the basic circuit of the present invention. The apparatus includes two variable capacitors **C1** and **C2** that are mechanically connected together so that the capacitance of each varies in an alternating manner. When the capacitance of **C1** is at a maximum, the capacitance of **C2** is at a minimum, and when the capacitance of **C2** is at a maximum, the capacitance of **C1** is at a minimum. The capacitance of these capacitors is on the order of 10,000 picofarads.

FIG. **2** illustrates the construction of the two capacitors **C1**, **C2**. The capacitors are formed in a wall of a container **12** for holding a fluid **20**. The other walls of the container are electrically conductive and the container is fluid tight. Each capacitor includes a separate stationary conductor **14, 14'**. These conductors are two metal plates that are positioned at the extreme ends of the motion of a moving conductor **18**. The moving conductor serves as a common capacitor plate to both capacitors. In the preferred embodiment the moving conductor is a drop of mercury. The two variable capacitors also share a common dielectric member **16**. The two stationary conductors are rigidly attached to the bottom surface of the dielectric member **16**. The moving conductor **18** slides back and forth within the container **12** and on top of the dielectric member **16**. The capacitors **C1** and **C2** are formed by the dielectric member **16**, the common conductor **18**, and the separate stationary conductors **14, 14'**. The circuit illustrated in FIG. **1** is connected to the apparatus of FIG. **2** at points A, E, and F, as indicated in FIG. **2**.

The movable conductor **18** is surrounded by a fluid **20** which raises the breakdown voltage of the two capacitors. This fluid is retained in the container **12** and is selected to have very low conductivity and high breakdown voltage.

It has been observed that when atmospheric air is used between the capacitor plates of an electrostatic generator, the air ionizes at high voltages and reduces the efficiency of the generator. This ionization can be explained with the help of FIG. **3**. When the drop of mercury **18** moves from left to right, the trailing edge of the mercury continuously uncovers a small wedge-shaped gap **22**. In this gap, the force of the electric field is intensified because of the narrow dimensions. The field causes the thin film of air in the gap to ionize. When the air ionizes, the negative ions are attracted to the positively charged mercury drop **18** and the positive ions are attracted to the upper surface of the dielectric member **16** by the negatively charged plates **14, 14'**. These ionized particles tend to maintain a potential on the dielectric surface approaching that of the mercury, thus significantly reducing the transfer of charge between the plates of the capacitors.

The wedge-shaped gap **22** at the edge of the mercury drop can also be visualized as one of two dielectrics connected in series. One dielectric is the film of air in the gap and the other is the dielectric member **16**. In the

preferred embodiment the dielectric member is fabricated from Mylar. Since the breakdown voltage of Mylar is substantially more than the breakdown voltage for atmospheric air, the air ionizes long before the maximum electric field corresponding to the Mylar can be developed across the capacitor plates.

To avoid this problem, a fluid **20** having a high breakdown voltage is used to surround the mercury drop and to eliminate the narrow gaps between the capacitor plates. The fluid also must have very low electrical conductivity in order to prevent any of the charge on the mercury **18** from leaking through the fluid **20** and reaching the surface of the dielectric member **16**. This leakage charge, like the ionized air particles, tends to cancel the charge transfer between the capacitors.

Mylar has a breakdown voltage of about 5,000 volts/-mil. It is believed that a fluid having a breakdown voltage of at least 1,000 v/mil and a resistivity of at least 10^{12} ohm-cm would be satisfactory in a biased system. One fluid having these characteristics is the oil used in commercial high power electrical transformers. For example, the Diola Ax oil obtained from the Shell Oil Company has been used in one embodiment actually constructed. Gases such as Freon and helium can also be used to increase the breakdown voltage. In addition, since the breakdown voltage of a gas is typically directly proportional to its pressure, filling the fluid container **12** with a low conductivity gas at high pressure would also prevent ionization.

In the preferred embodiment, the fluid **20** in the container **12** is also selected to enhance the triboelectric generation of charge. The triboelectric effect described above induces the deposition of negative charges on the upper surface of the dielectric member **16**. In FIG. **4** these charges are indicated by reference numeral **24**. When one negative triboelectric induced charge is positioned on the upper surface of the dielectric member **16**, a corresponding positive charge **25** is bound opposite to it on the surface of the stationary conductor **14**. Since the conductor is electrically neutral across its surface, there is an additional negative charge **26** which is bound opposite to the positive charge left on the mercury, when charge **24** was deposited. The net result of triboelectric charge generation is the addition of negative charges to the capacitors **C1** and **C2**.

With each increment of motion of the mercury **18** from left to right, as illustrated in FIG. **4**, an equal amount of charge is deposited on the surface of the dielectric member **16**. This deposition of charge causes an increase in the overall charge on capacitor **C1** as described above. Concurrently with this increase in charge, the capacitance of the capacitor is decreasing because of the motion of the mercury conductor. The voltage V1 across a capacitor C1 is a function of the following expression:

$$V1 = \frac{K(C_{max} - C_1)}{C_1}$$

Where K is a constant representing the amount of charge triboelectrically generated for each increment of capacitance reduction C_1 is the instantaneous capacitance of the capacitor, and C_{max} is the maximum value of C_1 when the motion of the mercury starts.

It has been observed that a fluid having low electrical conductivity and low viscosity can substantially increase the triboelectric generation of charge. A fluid of low conductivity is preferred in order to prevent the leakage of charge from the mercury drop **18** to the surface of the dielectric member **16** as described above. A fluid having low viscosity is preferred because the frictional contact between the mercury drop and the dielectric member is increased. It is believed that the rubbing contact between the movable conductor and the dielectric member causes the triboelectric effect to occur. A low viscosity fluid is also preferred in order to prevent the fluid from lubricating the mercury. It is also believed that a fluid having a resistivity of at least 10^{15} ohm-cm and a viscosity of less than 600 centistokes will satisfy these requirements.

One fluid having low viscosity, a high breakdown voltage and low electrical conductivity is Dimethylpolysiloxane. This fluid is obtainable from the Dow Corning Corporation of Midland, Michigan 48640. This fluid has a resistivity of 10^{15} ohms-cms, a dielectric strength of 35kv/100 mil, and a viscosity of 0.65 centistokes. When used in one embodiment of the present invention that was actually constructed, this fluid generated a bias of approximately 1,000 volts across a 6 um layer of Mylar. This voltage was sufficient to bias the variable capacitors C1 and C2 and to eliminate the need for a separate bias supply.

The present invention contemplates an electrostatic generator for producing electrical power. One application of this generation of power is for charging storage batteries. Referring to FIG. **1**, the circuit is connected to a rechargeable battery indicated by reference letters V_B. The rechargeable battery has an operating voltage, depending on its construction, of approximately 1.3 to 1.7 volts. Although any suitable rechargeable battery can be used, a nickel cadmium battery is preferred for electronic watch circuits. In FIG. **1** the rechargeable battery is connected in series with a load **28** representing the operating mechanism of the watch.

Connected across the battery V_B in parallel with the load **28** are two diodes, D1 and D2. The cathode of diode D1 is connected to the positive side of the battery, and the cathode of diode D2 is connected to the anode of diode D1. The anode of diode D2 is connected across the battery and in parallel with both the load **28** and the diodes, D1 and D2, are two other diodes, D3 and D4. The cathode of diode D3 is connected to the positive side of the battery, and the cathode of diode D4 is connected to the negative side of the battery. The diodes are selected to have low leakage in order to increase the efficiency of the circuit. The four diodes D1–D4 form a rectifier circuit that converts the AC output from the two variable capacitors C1, C2 into a DC output for charging the battery V_B.

In the preferred embodiment, a liquid mercury moving conductor **18** is preferred for several reasons. Because of its high density, the mercury maximizes the conversion of available work into electrical energy. When made of mercury, the moving conductor **18** performs more work in a limited space with minimum motion. Mercury is also preferred because it has high surface tension. During operation the moving conductor is subjected to large acceleration forces and a large electrostatic field. The high surface tension of mercury prevents the liquid drop from breaking up into a plurality of small droplets. These small droplets would retain a charge of their own, and the capacitor, in effect, would lose its power generating capability.

To maximize the generation of power an electrostatic generator must maximize the stored electrical energy per unit of surface area of each capacitor. The stored electrical energy in a capacitor is proportional to CV^2, where C is the capacitance of the capacitor and V is the voltage induced across the plates. The capacitance C is proportional to the dielectric constant of the dielectric material and is inversely proportional to its thickness. The voltage V is proportional to the breakdown voltage of the dielectric material. It has been observed that the breakdown voltage for most dielectric materials is proportional to the square root of the thickness of the dielectric. Thus, the electrical energy stored in a capacitor tends to be constant regardless of the thickness of the dielectric material. In the present invention the preferred dielectric material is one which has the highest product of dielectric constant and the square of the breakdown voltage for a given thickness.

A practical means to maximize the generation of power and the amount of energy stored in the capacitors without operating at bias voltages that are too high is to use very thin dielectric materials. For example, the dielectric member **16** can be fabricated from Mylar. In its thinnest presently available commercial form, Mylar has a breakdown voltage of approximately 1,000 volts. An additional, perhaps more suitable dielectric material, is Parylene, obtainable from the Union Carbide Company. A one micron thick layer of Parylene has the breakdown voltage of approximately 500 volts. Thus, Parylene permits the storage of very high energy without requiring a high bias voltage.

The electrostatic generator is operated by subjecting the container **12** and the moving conductor **18** to either random or cyclical forces. These forces can be acceleration forces that either operate directly on the mercury to cause it to slide back and forth or gravitational forces that generate potential energy that is expended in moving the mercury. In the embodiment designed for electronic watches, these forces are provided by the random motion of the watch wearer's wrist. At all times the mercury is free to slide within the container and is only constrained by the dimensions of the container.

In order to describe the operation of the circuit illustrated in FIG. **1**, assume as initial conditions that there is a bias voltage of −500 volts on point A. This bias voltage is obtained from either the triboelectric effect or from a separate bias supply as described below. The voltage across the battery V_B is approximately 1.7 volts. The capacitance of capacitor C1 is at its maximum value and the capacitance of capacitor C2 is nearly zero. The electrical charge Q on the capacitor C1 is given according to the following equation $Q_1 = C_1V$, and the energy stored therein is given by the following equation $E_1 = C_1V^2$.

The energy stored in the capacitors C1 and C2 is transferred by the motion of the mercury **18** in a manner to inversely alternate the capacitance of capacitors C1 and C2. When the capacitance of capacitor C1 is decreased and the capacitance of C2 is increased, the voltage at point F (FIG. **1**) becomes positive relative to the voltage at point A. In addition, the voltage at point E becomes negative with respect to the voltage at point A. This change in voltage occurs because both capacitors attempt to maintain the quantity of charge on their plates unchanged. Since the capacitance of C1 has decreased, the voltage across C1 must increase in order to maintain the quantity of charge of Q1 at a constant value. When the voltage across C1 has increased sufficiently, the diode D1 becomes forward biased and current flows through D1. The current path is through diode D1, into the positive side of the battery V_B, and through diode D4 to point E. The common terminal point A has no net current flowing through it after it is initially charged. Simultaneously, the capacitance of capacitor C2 is increasing in value and tends to forward bias diode D4. Capacitor C2 tends to drive point F more positive and point E more negative. In summary, as the capacitance of capacitor C1 decreases from its maximum value to zero, the electric charge Q on capacitor C1 is actually transferred from point F through the battery V_B to point E and, thus, the battery is charged by this current.

The energy stored in the capacitors C1 and C2 is transferred back in a cycle that is the reverse of the hereinbefore described sequence. As initial conditions assume that there is a bias voltage at point A of −500 volts and the voltage across the battery is approximately 1.7 volts. The capacitance of capacitor C1 is at a minimum value and the capacitance of capacitor C2 is at a maximum value. Capacitor C2 contains an electronic charge given by the equation $Q2 = C_2V$.

When the mechanical motion, hereinafter described, causes the capacitance of capacitor C2 to decrease, the voltage at point E becomes positive relative to the voltage at point A. Simultaneously, the capacitance of capacitor C1 tends to increase and the voltage at point F tends to go negative. As before both capacitors initially try to maintain the quantity of charge on their plates unchanged. When the voltage across C2 increases sufficiently, diode D3 becomes forward biased. The electric charge flows from point E through diode D3, into the positive side of the battery, and through the diode D2 to point F. The common terminal point A has no net current flowing through it.

It should be noted that in each part of the cycle there is a net current flow through the battery and this flow is always from the positive side to the negative side of the battery. Thus, battery charging current is produced regardless of which direction the values of capacitance are changing.

It should be further noted that the sum of the electric charges on points E and F remains unchanged throughout the cycle of capacitance change. Although there is a net production of energy which charges the battery, there is no loss of electric charge. The energy for charging the battery is generated by a moving conductor **18** that moves against the electrostatic forces caused by the voltage difference between points E and F.

Although the preferred embodiment incorporates a battery V_B, it should be appreciated that any suitable electrical energy storage device can be substituted for the battery V_B. Suitable energy storage devices are those that can store between cycles the electrical energy generated by mechanical motion and then can be discharged into the load. The construction and operation of the remainder of the circuit remains exactly the same. These storage devices include, for example, a large capacitor that is charged up by the current flow and then discharged into the load. The large capacitor replaces the battery V_B and is connected at the same point in the circuit, FIG. **1**. In like manner, the battery V_B can also be replaced by a DC motor connected to a fly wheel. The electrical energy generated by the circuit drives the DC motor and attached fly wheel thereby storing the generated electrical energy as kinetic energy. The stored energy can be recovered by a DC or AC generator also connected and driven by the fly wheel.

Another suitable electrical energy storage device that can be substituted for the battery V_B, FIG. **1** is a power distribution system. These distribution systems include the domestic power systems operated by public utilities and the private systems operated on ships and in independent commercial installations. When operating, a power distribution system is a short term, energy storage device because of the transmission time through the system between the energy generator and the load. In effect, the energy generator charges up the transmission lines and after a short period of time, the lines discharge into the load. In some cases there can be hundreds of miles of transmission lines between the generator and the load and the transmission time can be quite substantial. In addition, a power distribution system acts as a buffer between the energy generator and the load. In most applications the load varies continuously and correspondingly changes the power demanded from the generator. The distribution system smooths out the fluctuations in power demand. This operation of the distribution system as a buffer between the energy generator and the load is comparable to the operation of the battery V_B described hereinbefore.

To provide sufficient charging current for a power distribution system, a plurality of simultaneously operating energy generators are used and their outputs are connected to a conventional DC to AC converter. For example, a large number of energy generators can be floated on the surface of the ocean and accelerated by the motion of the ocean waves. The generators are disbursed over a wide area so that at any instant in time each energy generator is undergoing a different acceleration force. The energy generators are all connected in common to a DC/AC converter so that a nearly continuous AC output is obtained. This AC output is connected to the power distribution system and the electrical energy is thereby stored and transmitted to the load.

Although the preferred embodiment incorporates a battery V_B, it also should be appreciated that the circuit of FIG. **1** can be operated without a battery or an energy storage device. The two variable capacitors C1 and C2 and the four diodes D1–D4 form an electrostatic power generator and can be connected directly to a load as illustrated in FIG. **1**.

Although the triboelectric effect described above can develop sufficient voltage to bias the circuit of FIG. **1**, less severe requirements on the fluid surrounding the moving conductor can be applied by pre-charging the two variable capacitors C1 and C2 to a high voltage. To pre-charge the variable capacitors, the pulse transformer circuit illustrated in FIG. **1** is used to apply a high voltage across both variable capacitors. When point G is given a positive pulse, the transistor Q1 and the transformer generate a high voltage which is rectified through diode D5. A conventional blocking oscillator can also be used to charge the variable capacitors.

It has also been observed that when some fluids are used in the container, there is a certain amount of charge leakage between the moving conductor **18** and the dielectric member **16**. One example of such a fluid is transformer oil that has been contaminated by water. This leakage causes electrical charges to accumulate on the surface of the dielectric member **16** and to neutralize the electrostatic field between the plates of the two capacitors. This leakage is a problem because it decreases the efficiency of power generation.

Referring to FIG. **1**, the circuit including transistor Q2 is used to discharge the two capacitors C1, C2 and to remove the build up of charge on the capacitor plates due to charge leakage through the fluid **20**. When transistor Q2 is pulsed at point H, capacitors C1 and C2 are discharged through diodes D1 and D3.

To increase the energy exchange between capacitors C1 and C2 in FIG. **1** and thereby the charging energy to the load, an impedance matching arrangement is used. This may take the form of a DC/DC converter **30**, FIG. **5** for converting the high voltage differentials between points K and L, FIG. **1**, to a low voltage, high current output applied to the battery and the load.

It should also be noted that if the load or the electrical energy storage device can be charged using AC power, then the diodes D1–D4 are not required. Thus, the circuit of FIG. **6** is used for an AC load. This circuit merely comprises the two variable capacitors C1 and C2 connected in series, and the AC load is placed across points E, F of FIG. **6**. The construction and operation of the two capacitors is the same as described above.

In addition, although mercury is disclosed in the preferred embodiment, any conductive liquid or solid can be used for the moving conductor **18**.

It is also contemplated that the present invention is operable in all battery power equipment subjected to mechanical motion. This type of equipment includes electronic wrist watches, portable radios, hearing aids, cardiac pacemakers, small portable calculators, navigational buoys, other water borne equipment, and vehicular mounted electronic equipment.

Thus, although the best mode contemplated for carrying out the present invention has been herein shown and described, it will be apparent that modification and variation may be made without departing from what is regarded to be the subject matter of the invention.

What is claimed is:

1. Apparatus for electrostatically generating power by converting mechanical motion into electrical energy, comprising:

(a) a container for fluid;

(b) two variable capacitors formed in the container, said capacitors each having a separate conductor and sharing a common dielectric member and a common movable conductor, said common conductor is separated from the separate conductors by the dielectric member, moves between the separate conductors in response to mechanical motion, and thereby inversely alternates the capacitance between the two variable capacitors;

(c) an output power increasing, electrically resistive fluid held within the container and in contact with the common conductor and the common dielectric member; said fluid having a breakdown voltage substantially greater than atmospheric air;

(d) circuit means connected to the common conductor and the separate conductors for transferring charge between the variable capacitors and having two output junctions for transmitting electrostatically generated power.

2. An apparatus as in claim **1** in which the fluid has a breakdown voltage of at least 1,000 volts per mil.

3. Apparatus for electrostatically generating power by converting mechanical motion into electrical energy, comprising:

(a) a container for fluid;

(b) two variable capacitors formed in the container, said capacitors each having a separate conductor and sharing a common dielectric member and a common movable conductor, said common conductor is separated from the separate conductors by the dielectric member, moves between the separate conductors in response to mechanical motion, and thereby inversely alternates the capacitance between the two variable capacitors;

(c) a capacitor breakdown voltage increasing fluid held within the container and in contact with the common conductor and the common dielectric member, said fluid having a breakdown voltage substantially greater than atmospheric air and resistivity of greater than 10^{12} ohm- centimeters; and

(d) circuit means connected to the common conductor and the separate conductors for transferring charge between the variable capacitors and having two output junctions for transmitting electrostatically generated power.

4. An apparatus as in claim **3** in which the breakdown voltage increasing fluid has a breakdown voltage of at least 1,000 V/mil.

5. An apparatus as in claim **3** in which the breakdown voltage increasing fluid is transformer oil.

6. An apparatus as in claim **3** in which the breakdown voltage increasing fluid is Dimethypolysiloxane.

7. An apparatus as in claim **3** in which the breakdown voltage increasing fluid is Freon.

8. An apparatus as in claim **3** in which the breakdown voltage increasing fluid is helium.

9. An apparatus as in claim **3** in which the common conductor is an electrically conductive liquid connected to the circuit means.

10. An apparatus as in claim **3** in which the common conductor is a drop of mercury.

11. An apparatus as in claim **3** in which means for pre-charging the variable capacitors is connected to the circuit means.

12. An apparatus as in claim **3** in which means for discharging the variable capacitors is connected to the circuit means.

13. Apparatus for electrostatically generating power by converting mechanical motion into electrical energy, comprising:

(a) a container for fluid;

(b) two variable capacitors formed in the container, said capacitors each having a separate conductor and sharing a common dielectric member and a common movable conductor, said common conductor is separated from the separate conductors by the dielectric member, moves between the separate conductors in response to mechanical motion, and thereby inversely alternates the capacitance between the two variable capacitors;

(c) a triboelectric charge generating fluid held within the container and in contact with the common conductor and the common dielectric member, said fluid in combination with the movable conductor generates sufficient charge to bias the variable capacitors, said fluid also has a resistivity substantially greater than atmospheric air; and p1 (d) circuit means connected to the common conductor and the separate conductors for transferring charge between the variable capacitors and having two output junctions for transmitting electrostatically generated power.

14. An apparatus as in claim **13** in which the charge generating fluid has a resistivity of at least 10^{15} ohm-cms and a viscosity of less than 600 centistokes.

15. An apparatus as in claim **13** in which the charge generating fluid is Dimethylpolysiloxane.

16. An apparatus as in claim 13 in which the common movable conductor is an electrically conductive liquid connected to the circuit means.

17. An apparatus as in claim 13 in which the common conductor is a drop of mercury.

18. An apparatus as in claim 13 in which means for pre-charging the variable capacitors is connected to the circuit means.

19. An apparatus as in claim 13 in which means for discharging the variable capacitors is connected to the circuit means.

20. Apparatus for charging an electrical energy storage means by converting mechanical motion into electrical energy, comprising:

(a) an electrical energy storage means chargeable by passing a charging current therethrough;

(b) first and second diode means connected across said energy storage means;

(c) third and fourth diode means connected across an energy source, said first and second diode means being connected in parallel with said third and fourth diode means and all of said beforementioned diode means being forward biased with respect to the charging current;

(d) two variable capacitors each having a separate conductor and sharing a common dielectric member and a common movable conductor, one separate conductor being connected between the first and second diode means and the other separate conductor being connected between the third and fourth diode means, said common conductor is separated from the separate conductors by the dielectric member, moves between the separate conductors in response to mechanical motion, and thereby inversely alternates the capacitance between the two variable capacitors; and

(e) an output power increasing, electrically resistive fluid held within the two variable capacitors and in contact with the common conductor and the common dielectric member, said fluid having a resistivity substantially greater than atmospheric air.

21. An apparatus as in claim 20 in which the fluid is a capacitor breakdown voltage increasing fluid.

22. An apparatus as in claim 20 in which the fluid is a triboelectric charge generating fluid.

23. An apparatus as in claim 20 in which the electrical energy storage means is a rechargeable DC energy source.

24. An apparatus as in claim 20 in which the electrical energy storage means is a battery.

25. An apparatus as in claim 20 in which the electrical energy storage means is a capacitor that can be charged-up by the variable capacitors and can be discharged into a load.

26. An apparatus as in claim 20 in which the electrical energy storage means is a fly-wheel rotated by a DC motor.

27. An apparatus as in claim 20 in which the electrical energy storage means is a power distribution system.

28. Method for electrostatically generating power by converting mechanical motion into electrical energy, comprising the steps of:

(a) triboelectrically charging first and second variable capacitors with a quantity of electrical charge;

(b) generating an electrostatic force field in the first capacitor;

(c) moving a body against the electrostatic force field in the first capacitor so that charge is transferred through a circuit from the first capacitor to the second capacitor;

(d) generating an electrostatic force field in the second capacitor; and

(e) moving the body against the electrostatic force field in the second capacitor so that charge is transferred from the second capacitor back to the first capacitor through the circuit, whereby said transfer of charge between the variable capacitors is the electrostatically generated power.

29. A method as in claim 28 in which the first and second variable capacitors are triboelectrically charged by relative motion between a dielectric material, the moving body, and a fluid in contact with both.

SENSOR SYSTEM WITH ENERGY HARVESTING

STATEMENT OF RELATED CASES

[0001] This case claims priority of U.S. Pat. App. Ser. No. 62/388,989 filed Feb. 16, 2016 and which is incorporated herein by reference.

FIELD OF THE INVENTION

[0002] This invention relates generally to harvesting environmental energy, and more particularly to harvesting energy from RF signals for powering very low power sensors.

BACKGROUND OF THE INVENTION

[0003] In many sensor applications, the sensors operate at very low power levels—as low as microwatts and even nanowatts. Such applications often require that the sensors be incorporated into wireless networks and operate with minimal power supplies. Power supplies that include energy-harvesting technology compatible with the aforementioned ultra-low power levels are, in some cases, used to provide power in these applications.

[0004] FIG. **1** depicts an energy-harvesting system disclosed in U.S. Pat. No. 7,084,605. Energy-harvesting system **100** includes energy-harvesting antenna **102**, inductive element **104**, variable capacitive element **106**, rectifier **108**, intermediate storage capacitor **110**, switch **112**, control circuitry **116**, DC energy output **114**, final energy-storage device **118**.

[0005] Energy-harvesting system **100** operates to charge final energy-storage device **118**. Inductive element **104** and variable capacitive element **106** form a tuning circuit to maximize the amount of energy harvested from the environment. Rectifier **108** converts the RF or AC energy received from antenna **102** into a DC energy, which is stored in capacitor **110**. Switch **112** controls the flow of DC energy **114** from storage capacitor **110** to final energy storage device **118**. The switch provides energy to operate electronic devices at fixed time intervals while also storing any additional unused energy on final energy storage device **118**. Switch **112** also functions to provide an input to control circuitry **116** to tune circuit elements **104** and **106** for best energy harvesting.

[0006] FIG. **2** depicts an energy-harvesting system for use with a wireless sensor, as disclosed in U.S. Pat. No. 8,552,597. Energy-harvesting system **200** includes energy-harvesting antenna **220**, super capacitor **222**, DC/DC converter **224**, battery and charger **226**, and power switch **228**. System **200** is directly connected to sensor node **230** and communications antenna **232**. The system can be bandpass or all-pass filtered to match all AM frequencies to maximize the capture of harvestable energy to the extent possible. Supercapacitor **222** provides a buffer for rechargeable battery **226**. Harvested energy can be used to power sensor node **230** or charge the sensor node's local power source **226**. The system is disclosed to provide power of over 10 mW to load devices.

SUMMARY

[0007] The present invention provides a source of switched DC power for a variety of sensor and control systems, including, without limitation, biomedical devices and remote and/or portable environmental sensors.

[0008] The illustrative embodiment of the invention is a sensor system including a primary load circuit with energy harvesting. In the illustrative embodiment, the primary load circuit is an RFID transponder, which can be structured for operation over a frequency range from about 100 kHz up to about 40 GHz and in accordance with any number of protocols including IEEE 802.15.4, ISO 18000, IEEE 802.15.1 (Bluetooth), and IEEE 802.11 (Wi-Fi). In one embodiment, the system is used to wake-up and/or synchronize a battery-powered UHF communication node within a network having a plurality of such nodes. By virtue of the invention and, in particularly, the manner in which energy harvesting is implemented, the distance between a transponder (included in the sensor system) and a remote interrogator is greatly increased compared to the prior art.

[0009] In accordance with an illustrative embodiment, the system includes an antenna, an impedance-matching network, an RF switch, inductive and diode components (for forming a resonant RF-to-DC voltage multiplication circuit in conjunction with other elements of the system), a DC switch, an energy-storage device, and a primary load circuit.

[0010] In accordance with the illustrative embodiment and unlike the prior art, the same antenna is used for both harvesting RF energy and for communications (e.g., RFID transponder communications, etc.). This reduces the size of the sensor system. In some embodiments, the antenna is a multi-band antenna.

[0011] In operation of some embodiments of the invention, incident RF energy that excites the antenna is coupled, at different times, into one of: (1) the energy storage device (e.g., capacitor, rechargeable battery, etc.) or (2) the primary load circuit. The destination for the harvested energy depends upon the state of the system. More particularly, the RF switch operates to direct the harvested energy to the energy storage device until a pre-determined "high" threshold is exceeded. In the illustrative embodiment, this high threshold is a specified voltage measured across the energy storage device.

[0012] Energy harvesting is implemented via a resonant voltage multiplication circuit. This circuit enables energy to be stored at a voltage level higher than is possible without the multiplier. The resonant voltage multiplication circuit permits harvesting charge in nano and microJoule increments. Typical circuits providing an RF-to-DC voltage multiplier include a diode rectifier and a DC-to-DC up-converter. These circuits do not operate at nanoWatt power levels. The voltage multiplication circuit is a resonant LC loop, wherein the capacitance of a semiconductor rectifying diode determines the resonant frequency of the voltage multiplier. This same diode, which in the illustrative embodiment is a Schottky diode, provides the unidirectional charging current to the energy storage element.

[0013] When the high voltage threshold is exceeded, in some embodiments, the DC switch enables harvested energy from the energy storage device to flow to the primary load circuit. Also, the state of the RF switch changes so that voltage multiplication is disconnected and the primary load circuit is coupled to the antenna for communications. The DC switch continues to electrically couple the energy storage device to the primary load circuit until the energy available from the energy storage device drops below a "low" voltage threshold. When the voltage drops below this low threshold, the RF switch and DC switch change state to enable energy harvesting and disconnect the primary load circuit from the antenna. Thus, in the illustrative embodiment, the system cycles between these two modes of operation as a function of the voltage across the energy storage device.

[0014] The impedance-matching circuit ensures that the RF impedance presented to the antenna by the voltage multiplier and the impedance presented to the antenna by the primary load circuit is the same. Impedance matching provides the maximum RF power transfer between the antenna and the primary load circuit, therefore providing a maximum range for the separation distance between, for example, an RFID transponder (as an example of the primary load circuit) and an RFID interrogator.

[0015] In some other embodiments, the sensor system includes one or more of the following:

- **[0016]** secondary load circuit(s) and tertiary load circuit(s), such as and without limitation, additional sensors (such as sensors for temperature, humidity, electrical conductivity, corrosion, media permittivity, inertial motion, fluid acidity, heartbeat rate, breath rate, magnetic field, gravitational vector force, and localized imaging), microprocessors, Internet connections, optical communications links, and actuatable control devices;
- **[0017]** additional control circuits;
- **[0018]** one or more batteries;
- **[0019]** devices/circuits that are operable to tune the operation at different frequencies; and
- **[0020]** devices/circuits that harvest RF energy at frequencies in addition to the operational RFID communications frequency.

[0021] In addition to its dual-purpose antenna, embodiments of the inventions include one or more of the following innovations, among any others:

- **[0022]** Power is supplied to the primary load circuit only when the energy that is harvested reaches a threshold level. In other words, the energy harvesting circuit and the primary load circuit are electrically coupled to the antenna at different times. This eliminates the undesirable loading effect of the energy harvesting circuit on the antenna that would otherwise occur if these two circuits were connected to the antenna at the same time. This enables the primary load circuit—the RFID transponder in the illustrative embodiment—to operate with lower ambient RF power levels.
- **[0023]** The energy-harvesting loop provides resonant, rectifying voltage multiplication. The resonant characteristic of the harvesting loop permits direct charging of the energy storage device to a higher voltage than is possible with a non-resonant loop. Not used in prior-art RFID systems, this permits charging of the energy storage device with incident RF power levels that are an order of magnitude smaller than required to operate an RFID transponder.
- **[0024]** In this regard, the prior-art system depicted in FIG. **1** includes a resonant circuit, but this is a parallel, resonant-circuit connection that does not enable directly charging the final energy storage device **118** to a voltage greater than the RF voltage provided by antenna **102**. Again, in embodiments of the present invention, the series resonant loop circuit including the resonant voltage multiplier is capable of charging the energy storage device to a voltage level that is greater than the RF voltage received from the antenna.
- **[0025]** The prior-art system depicted in FIG. **2** depicts a DC/DC converter **224**, which increases the DC voltage available from capacitor **222**. This converter is generally used to step-up the harvested DC voltage. However, such converters do not operate at the power levels of interest for embodiments of the present invention. In particular, typical RFID transponders operate at microwatt power levels. The inventor's use of the resonant voltage multiplier enables embodiments of the present invention to harvest RF power at nanoWatt levels, as enabled by the increased RF-to-DC voltage conversion.

[0026] In some embodiments, the sensor system harvests RF power from a single RF source, such as an RFID interrogator, at a single frequency. In some other embodiments, the sensor system is powered from multiple RF sources at multiple frequencies. In embodiments in which power is obtained from multiple RF sources, the sensor system includes a multi-frequency antenna, such as is disclosed in U.S. Pat. Nos. 8,581,793, 9,160,079, and 9,160,070, and matched resonant voltage multiplication circuits, that incrementally charge a single energy storage device (e.g., capacitor, etc.). For example, in one embodiment, the sensor system is configured with resonant harvesting circuits for multiple frequencies such as 1 MHz, 98 MHz and 915 MHz, whereas the primary load circuit, embodied as an RFID transponder, operates only within the 915 MHz band. The sensor system, however, is capable of harvesting power from all three wavelength bands to power the RFID transponder.

[0027] It will often be the case for such embodiments that energy is harvested from an RF energy source that, although readily available as a harvesting source, is not at the preferred frequency of the primary load circuit (e.g., not at the frequency preferred for RFID interrogation). In some of such embodiments, one or more harvesting circuits are provided to charge the energy storage device more or less continuously from ambient RF energy in the environment, such as a commercial AM, FM or TV broadcast station. In some embodiments, the energy storage device is maintained at a substantially "full" level of charge as a result of accumulated harvesting. The primary load circuit (e.g., RFID transponder) may operate in any of several available unlicensed frequency bands such as 125 kHz, 13.56 MHz, 860-960 MHz, or 2.45 GHz while the energy harvester is powered from other RF sources such as AM, FM or TV broadcast stations. In embodiments of the present invention, the energy harvesting circuits do not load the micro-power RFID transponder when it is enabled.

BRIEF DESCRIPTION OF THE DRAWINGS

[0028] FIG. **1** depicts a first prior-art energy harvesting system.

[0029] FIG. **2** depicts a second prior-art energy harvesting system.

[0030] FIGS. **3**A and **3**B depict a block diagram of a sensor system in accordance with an illustrative embodiment of the present invention.

[0031] FIG. **4**A depicts an embodiment of the sensor system of FIGS. **3**A/**3**B.

[0032] FIG. **4**B depicts an embodiment of the sensor system of FIGS. **3**A/**3**B wherein plural harvester circuits tuned for different frequencies and all charging the same energy storage device simultaneously are included.

[0033] FIG. **5** depicts an embodiment of the sensor system of FIGS. **3**A/**3**B wherein RF switching is controlled by a Schmitt gate and a transfer gate.

[0034] FIG. **6** depicts the control voltage and functions of sensor system of FIG. **5**.

[0035] FIG. **7** depicts an embodiment of the sensor system of FIGS. **3**A/**3**B with a secondary load circuit and programmed control connection to a battery power source.

[0036] FIG. **8** depicts an embodiment of the sensor system of FIGS. **3**A/**3**B with secondary load circuits and a delay connection to a battery power source for a timed interval.

[0037] FIG. **9** depicts an embodiment of the sensor system of FIGS. **3**A/**3**B with secondary load circuits and external devices wherein a battery power source is connected to the secondary load circuits under programmed control from the first load circuit.

[0038] FIG. **10** depicts an embodiment of the sensor system of FIGS. **3**A/**3**B wherein the impedance matching network is a T-match filter.

[0039] FIG. **11**A depicts and embodiment of the sensor system of FIGS. **3**A/**3**B wherein the RF frequency for operation is tuned by a variable capacitance device under programmed control.

[0040] FIG. **11**B depicts an embodiment of the variable capacitance device used in the embodiment of FIG. **11**A.

DETAILED DESCRIPTION

[0041] The following terms and their inflected forms are explicitly defined for use in this disclosure and the appended claims:

[0042] "RFID device" means a communication sensor, operated in a passive, semi-passive, or active mode. The sensing function includes a means of self-identification and, in some embodiments, one or more environmental sensors, actuators, controllers, etc.

[0043] "Load circuit" means the portion of the sensor system that consumes power, such as, without limitation, integrated circuits, sensors, actuators, imagers, LEDs, and lasers.

[0044] "Semi-passive RFID" means an RFID device powered with a local DC source including harvested energy stored in an energy storage device and communicating with an external interrogator via means of reflected signal carrier.

[0045] FIGS. **3**A and **3**B depict a block diagram of sensor system **300** in accordance with the illustrative embodiment of the present invention. Sensor system **300** includes antenna **340**, impedance matching network **342**, RF switch **344**, Inductance and Diode components (partial RF-to-DC voltage multiplier circuit) **346**, DC switch **348**, energy storage device **350**, and primary load circuit **352**.

[0046] Sensor system **300** is characterized as having energy-harvesting circuit **336** and load-enabling circuit **338**, with some elements in common. Energy-harvesting circuit (or RF-to-DC voltage multiplier) **336** includes antenna **340**, impedance matching network **342**, RF switch **344**, inductance and diode components **346**, and energy storage device **350**. Load-enabling circuit **338** includes antenna **340**, impedance matching network **342**, RF switch **344**, DC switch **348**, energy storage device **350** and primary load circuit **352**.

[0047] Sensor system **300** receives RF power into impedance matching network **342** through antenna **340**. The RF voltage, which is output from impedance matching network **342**, is directed to either (the rest of) energy-harvesting circuit **336** or (the rest of) load-enabling circuit **338**, depending on the position of RF switch **344**. The position of the RF switch is a function of the state of sensor system **300**; in particular, the charge level of energy storage device **350**.

[0048] When RF switch **344** is in a first position, it enables energy harvesting. In this mode of operation, RF energy received through the antenna from a remote source charges energy storage device **350** until voltage V_R across its terminals exceeds a "high" threshold voltage level, as monitored by DC switch **348**. When the high voltage threshold is exceeded, the mode of operation changes; primary load circuit **352** is enabled via DC switch **348**. Specifically, the DC switch electrically couples energy storage device **350** to primary load circuit **352**, thereby supplying DC power thereto. This enables primary load circuit **352** for operation with the voltage $V_{DD}=V_R$. Also, during this same switching interval, RF switch **344** changes to a second position disconnecting the antenna from the energy harvesting circuit and connecting it to the primary load circuit.

[0049] FIGS. **4**A and **4**B depict an embodiment of sensor system **300** wherein antenna **340** is implemented by dipole antenna **440**, impedance matching network **342** is implemented via inductor L_{R1}, RF switch **340** is implemented by single-pole double-throw (SPDT) switch S_{RF}, groupings of inductive and diode components **346-1** to **346**-*n* are each implemented via an inductor and a Shottky diode (i.e., L_{R2} and D_{R1} through L_{Rn+1} and D_{Rn}, respectively), energy storage device **350** is implemented by capacitor C_1, and primary load circuit **352** is implemented as RFID transponder **452**.

[0050] The inductive and diode components **346-1** through **346**-*n* tune the respective harvesting circuits providing RF harvesting at n different frequencies such as a UHF waveband and a lower HF or LF band. The selected frequency bands should be adequately separated to avoid cross talk interference. It is within the capabilities of those skilled in the art to select appropriately separated frequencies to avoid cross talk.

[0051] In some embodiments, RF switch S_{RF} comprises a GaAs JFET transistor and a silicon NPN transistor each controlling the two arms of the SPDT switch. The JFET provides a low resistive impedance source-drain circuit path with zero gate-voltage bias for RF energy harvesting.

[0052] RF switch S_{RF}, at position "1" as depicted in FIGS. **4**A and **4**B, enables energy harvesting. The energy harvesting loop includes inductive RF-to-DC voltage multiplication, which provides significant benefits over the prior art. RF power received by antenna **440** is partially rectified by the Schottky diode(s). The energy-harvesting circuit is an RLC resonant loop; the capacitance of Schottky diode(s) resonates with the series loop inductance provided by (in FIG. **4***a*) inductors L_{R1}, L_{R2}, and antenna **440**. The harvesting loop resonates at the frequency of the external RF power source (e.g., RFID interrogator, etc.). The resonant characteristic of the harvesting loop enables charging the energy storage device to a higher voltage than is possible with a non-resonant circuit.

[0053] FIG. **5** depicts an embodiment of sensor system **300** wherein DC switch **348** is embodied as transfer gate TG_1, Schmitt gate SG, and resistors R_1 and R_2. In this embodiment, and all other embodiments depicted herein, RF switch S_{RF} is controlled by the DC switch. It is important to note that, due to this arrangement, primary load circuit **352**—RFID transponder **452** in the illustrative embodiments—does not receive DC power during those times when RF energy harvesting is enabled. Harvesting and transponder functions are enabled at different times through RF switch S_{RF}, which is itself controlled by the control voltage V_{DC}. In particular, when (harvested) voltage V_R (the voltage across the energy storage device) exceeds the high threshold level, control voltage V_{DC} enables the following:

[0054] (1) DC switch **348** connects the supply voltage V_R into RFID transponder **452** and actuates the RF switch S_{RF} from position **1** to position **2**.

[0055] (2) Due to the move from position **1** to position **2**, the energy harvesting circuit(s) are disabled.

[0056] (3) Due to the move from position **1** to position **2**, antenna **440** and its impedance matching network are connected to RFID transponder **452**.

RFID transponder **452** is made operational through this switching action and a wireless communication link is established with a remote RFID interrogator (not depicted), through antenna **440**.

[0057] The DC threshold sensing function is provided by DC switch **348**. With RF switch S_{RF} in position "**1**" for energy harvesting, the resonant voltage multiplier is enabled and capacitor C_1 charges. Energy harvesting is disabled when the voltage V_R across capacitor C_1 exceeds the pre-determined high threshold level, as determined by the voltage divider connection R_1 and R_2. When the voltage exceeds the threshold, Schmitt gate SG goes to a high state, supplying control voltage V_{DC} to transfer gate TG_1 and RF switch S_{RF}. The enabled transfer gate TG**1** causes the voltage level V_{DD} across RFID transponder to increase from a minimal value up to approximately V_R (the voltage level of "fully" charged capacitor C_1). Control voltage V_{DC} causes RF switch S_{RF} to move to position "**2**". There is a hysteresis in voltage V_{DC} provided from Schmitt gate SG that enables the direction connection $V_R=V_{DD}$ throughout the hysteresis range of the Schmitt gate.

[0058] Thus enabled, RFID transponder **452** continues to operate until the voltage V_R falls below a pre-determined lower threshold voltage, indicating that the energy storage device—capacitor C_1 in the illustrative embodiment—has drained to the point that it cannot sustain the operation of the RFID transponder. Schmitt gate SG responds when the voltage V_R falls below the lower voltage threshold and the control voltage V_{DC} goes low. The transfer gate TG_1 then stops the flow of energy to the primary load circuit—RFID transponder **452** in the illustrative embodiment—and causes RF switch S_{RF} to move to position **1**, thereby disconnecting the RFID transponder and re-establishing the energy harvesting circuit. The charging cycle then repeats, etc. In some other embodiments, voltage V_{DC} is supplied directly as V_{DD} into the primary load circuit **352** and transfer gate TG_1 is not used.

[0059] The high and low threshold voltages are determined from calibrations and designed into the DC switch circuit. A typical value for the high threshold is about 3.5 volts and a typical value for the low threshold is about 1.5 volts.

[0060] FIG. **6** depicts the sequence of harvesting operation T_H and RFID transponder operation T_P. The plot depicting voltage V_R across the energy storage device shows voltage V_R rising to a maximum V_R^{MAX} during the energy harvesting operation. Once the "high" threshold voltage is exceeded, control voltage V_{DC} goes high and stored energy from the energy storage device is directed to the RFID transponder. The plot depicting voltage V_{DD} across the transponder shows voltage V_{DD} at its peak value V_{DD}^{MAX} when the transponder is first switched in. As the energy storage device drains, supplying energy to the primary load circuit transponder, voltage V_{DD} falls along with voltage V_R. When the voltage across the energy storage device (i.e., capacitor C_1) falls past the low threshold voltage value V_R^{MIN}, at which point the voltage across the transponder reaches its minimum value V_{DD}^{MIN}, control voltage VDC goes low and energy harvesting operation T_H resumes.

[0061] FIG. **7** depicts an embodiment of sensor system **300** that includes secondary load circuit **752** and a data bus or control line **754** from RFID transponder **452** to the secondary load circuit. In this embodiment, secondary load circuit **752** is enabled via second transfer gate TG_2 and controlled from the RFID transponder. Second load circuit is enabled typically only during operation of the RFID transponder and thus energy drain from battery power source V_{BAT} is minimal. This embodiment is particularly useful for applications in which the available battery is very small and it is desirable to conserve its stored energy.

[0062] FIG. **8** depicts an embodiment of sensor system **300** that provides a delayed connection to battery power source V_{BAT} for a timed interval. In this embodiment, Schmitt gate SG provides a control voltage V_{DC} to control second transfer gate TG_2. The control circuit electrically couples battery V_{BAT} for powering both RFID transponder **452** and second load circuit **752** for a fixed interval of time. The circuit comprised of resistors R_3, R_4, capacitor C_2 and diode D_{R2} provide the voltage which enables the transfer gate TG_2 supplying the battery voltage V_{BAT} to both load circuits for a fixed time interval. This embodiment is particularly useful when RFID transponder **452** is used to control loads, such as secondary load circuit **752** (via data bus **754**) and tertiary load circuits **852** (via data and power bus **856**) requiring additional power and wherein the operational interval of the RFID transponder is extended in time.

[0063] FIG. **9** depicts an embodiment of sensor system **300** wherein external power source V^{ext}_{BAT} is continually supplying power to secondary load circuit **752**. The secondary load circuit is controlled via RFID transponder **452** over data bus **754**. In this embodiment, tertiary load circuits **852**, which are electrically connected to secondary load circuit **752** via data and power bus **856** can draw watts or even kilowatts from power source V^{ext}_{BAT}.

[0064] FIG. **10** depicts an embodiment of sensor system **300** in which impedance matching network **342** is implemented as T-match filter **1042**. This embodiment is suitable for UHF sensors (operating at frequencies in the range of 300 MHz to 3 GHz).

[0065] T-match filter **1042** can be made by patterning of metallization on printed circuit boards and flexible substrates. A typical T-match filter has an equivalent inductive impedance component that is compatible with the use of the impedance element (e.g., L_{R2}, etc.) in the RF-to-DC voltage multiplication circuit.

[0066] FIG. **11**A depicts an embodiment of sensor system **300** in which the RF frequency for operation is tuned by variable capacitance device C_{DIG} under the control of secondary load circuit **752** over data bus **1158**. In this embodiment, a controlled capacitance is connected across the output of impedance matching network L_{R1} to provide a desired impedance match to antenna **440**/impedance matching network L_{R1}. Small incremental changes in the capacitance of variable capacitance device C_{DIG} shift the resonant frequency of sensor system **300**. In some other embodiments, variable capacitance device C_{DIG} is under the autonomous control of RFID transponder **452**. In yet some additional embodiments, a remote RFID interrogator controls the capacitance through RFID transponder **452**.

[0067] FIG. **11**B depicts an embodiment of C_{DIG} for providing a variable capacitance. In this embodiment, capacitance is controlled with 4-bit digital data bus **1158**. In this circuit, each control bit changes the capacitance of respective varactor diodes D_{V1}, D_{V2}, D_{V3}, D_{V4}. The capacitances of the varactor diodes are much smaller than that of respective coupling capacitors C_3, C_4, C_5 and C_6. Respective resistors R_5, R_6, R_7, and R_8 have impedances that are much higher than the reactance of capacitors C_3 through C_6 and do not load the variable capacitor circuit. The sum of the parallel connection of varactor-diode capacitors biased under programmed bus control provides variable capacitor C_{DIG} that tunes the wireless sensor.

[0068] It is to be understood that although this disclosure teaches many examples of embodiments in accordance with the present teachings, many additional variations of the invention can easily be devised by those skilled in the art after reading this disclosure. As a consequence, the scope of the present invention is to be determined by the following claims.

What is claimed:

1. A sensor system comprising:

an RF front end that receives and switches RF energy;

an energy-harvesting circuit that provides resonant RF-to-DC voltage multiplication, the energy-harvesting circuit including:

(a) the RF front end,

(b) inductive and capacitive elements to provide a partially rectifying, resonant LC loop, and

(c) an energy storage device; and

a load-enabling circuit that powers a primary load circuit from the energy storage device, the load-enabling circuit including:

(a) the RF front end,

(b) the primary load circuit, and

(c) the energy storage device.

2. The sensor system of claim **1** wherein the RF front end comprises:

an antenna that both receives RF energy from ambient sources thereof and transmits signals originating from the primary load circuit;

an impedance matching network that is coupled to the antenna; and

an RF switch that switches the received RF energy between the energy-harvesting circuit and the load-enabling circuit.

3. The sensor system of claim **1** wherein the inductive and capacitive elements comprise an inductor and a Schottky diode connected in series.

4. The sensor system of claim **1** wherein the energy storage device is a capacitor or a rechargeable battery.

5. The sensor system of claim **1** wherein the load-enabling circuit further comprises a DC switch, wherein the DC switch is electrically coupled to the energy storage device and the primary load circuit.

6. The sensor system of claim **5** wherein the DC switch comprises a transfer gate and a Schmitt gate.

7. The sensor system of claim **5** wherein the DC switch comprises a Schmitt gate and is configured so that when a voltage across the energy storage device exceeds a first threshold, the Schmitt gate goes to a high state generating a DC control voltage.

8. The sensor system of claim **7** wherein the RF front end comprises an RF switch that switches received RF energy between the energy-harvesting circuit and the load-enabling circuit, and further wherein, when the control voltage is generated by the Schmitt gate:

(a) a DC supply voltage from the energy storage device is coupled into the primary load circuit; and

(b) the RF switch changes state, disabling energy harvesting and electrically coupling the primary load circuit to the RF front end.

9. The sensor system of claim **1** wherein the load-enabling circuit further includes a secondary load circuit, wherein the primary load circuit controls the secondary load circuit.

10. The sensor system of claim **2** further comprising a variable capacitive device electrically connected to the impedance matching network, wherein the variable capacitive device controls a resonance frequency of the sensor system, thereby dictating which frequencies of RF energy are harvested by the sensor system.

11. The sensor system of claim **2** wherein the antenna is a multi-band antenna, the RF front end further comprising plural groups of resonant energy-harvesting inductive and capacitive elements, each group tuned for a frequency band of the multi-band antenna, said respective energy-harvesting circuits all electrically coupled to a common energy storage device.

12. The sensor system of claim **1** wherein the primary load circuit is a RFID transponder.

13. A method for operating a sensor system, the method comprising:

receiving, at an antenna, RF energy from an ambient source of RF energy;

harvesting the received RF energy in an energy storage device via a circuit that provides resonant voltage multiplication;

when a voltage across the energy storage device exceeds a first threshold:

(a) electrically coupling the energy storage device to a primary load circuit, enabling energy to flow from the energy storage device to the primary load circuit, and

(b) changing the state of an RF switch, wherein the change in state:

  (i) decouples the circuit that provides resonant voltage multiplication from the antenna, and

  (ii) electrically couples the primary load circuit to the antenna so that the primary load circuit can transmit a signal;

when the voltage across the energy storage device drops below a second threshold:

(a) electrically decoupling the primary load circuit from the energy storage device,

(b) changing the state of the RF switch, wherein the change in state:

  (i) decouples the primary load circuit from the antenna; and

(ii) electrically couples the circuit that provides resonant voltage multiplication to the antenna so that RF energy is harvested.

14. The method of claim **13** wherein the source of RF energy is an RFID transponder.

15. A method for operating a sensor system, the method comprising switching between an energy harvesting mode and a load-enabling mode as follows:

enabling the energy harvesting mode when a voltage measured across an energy storage device falls below a first threshold voltage, the energy harvesting mode including:

(a) processing RF energy received at an antenna via resonant voltage multiplication, and

(b) storing the processed RF energy in the energy storage device; and

enabling the load-enabling mode when the voltage measured across the energy storage device exceeds a second threshold voltage, the load-enabling mode including:

(a) electrically couple the energy storage device to a primary load circuit, and

(b) transmitting a signal from the primary load circuit via the antenna.

16. The method of claim **15** and further wherein enabling the load-enabling mode further comprises:

(c) disabling the processing of the received RF energy, and

(d) electrically coupling the antenna to the primary load circuit.

17. The method of claim **15** and further wherein enabling the energy-harvesting mode further comprises:

(c) decoupling the primary load circuit from the energy storage device,

(d) decoupling the primary load circuit from the antenna, and

(e) coupling the antenna to inductive and capacitive elements that collectively provide resonant voltage multiplication.

18. The method of claim **15** wherein processing RF energy further comprises receiving RF energy sourced from plural sources, each source radiating RF energy at a different frequency, wherein the antenna is a multi-frequency antenna and the RF energy at each different frequency is processed by frequency matched resonant voltage multiplication circuits.

19. The method of claim **15** wherein enabling the load-enabling mode further comprises generating, from a Schottky diode, a control voltage that causes a transfer gate to electrically couple the energy storage device to the primary load circuit.

20. The method of claim **15** wherein enabling the load-enabling mode further comprises controlling, from the primary load circuit, a secondary load circuit.

(57) **ABSTRACT**

A radio frequency (RF) circuit comprises an antenna operably coupled to receive an RF signal, a power harvesting circuit operable to generate a first power source from the RF signal, a tank circuit coupled to the antenna and a tuning circuit. The tank circuit includes a selectively variable impedance and the tuning circuit is adapted to dynamically vary the selectively variable impedance of the tank circuit based on resonance of the RF circuit and frequency of the RF signal to substantially align the resonance of the RF circuit with the frequency of the RF signal. When the resonance of the RF circuit is substantially aligned with the frequency of the RF signal, the power harvesting circuit generates a second power source from the RF signal such that the second power source is greater than the first power source.

METHOD AND APPARATUS FOR DETECTING RF FIELD STRENGTH

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] The present U.S. Utility patent application claims priority pursuant to 35 U.S.C. §120 as a Continuation of U.S. Utility application Ser. No. 14/644,471, entitled "Method and Apparatus for Detecting RF Field Strength", filed 11 Mar. 2015, issuing as U.S. Pat. No. 9,704,085 on 11 Jul. 2017, which is a Continuation of U.S. Utility application Ser. No. 13/209,425, entitled "Method and Apparatus for Detecting RF Field Strength", filed 14 Aug. 2011, now U.S. Pat. No. 9,048,819, issued 2 Jun. 2015, which is a Continuation-In-Part of application Ser. No. 12/462,331, filed 1 Aug. 2009, now U.S. Pat. No. 8,081,043, issued 20 Dec. 2011 ("Related application"), which is in turn a Division of application Ser. No. 11/601,085, filed 18 Nov. 2006, now U.S. Pat. No. 7,586,385, issued 8 Sep. 2009 ("Related patent") (collectively, "Related References"). application Ser. No. 13/209,425 also claims priority pursuant to 35 U.S.C. §119(e) to U.S. Provisional Application No. 61/428,170, filed 29 Dec. 2010, and U.S. Provisional Application No. 61/485,732, filed 13 May 2011. The subject matter of the Related References, each in its entirety, is expressly incorporated herein by reference.

[0002] This application is related to application Ser. No. 13/209,420, filed on 14 Aug. 2011, now U.S. Pat. No. 8,749,319, issued 10 Jun. 2014 ("Related Co-application").

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0003] The present invention relates generally to detecting RF field strength, and, in particular, to detecting RF field strength in a passive RFID system.

2. Description of the Related Art

[0004] In general, in the descriptions that follow, we will italicize the first occurrence of each special term of art that should be familiar to those skilled in the art of radio frequency ("RF") communication systems. In addition, when we first introduce a term that we believe to be new or that we will use in a context that we believe to be new, we will bold the term and provide the definition that we intend to apply to that term. In addition, throughout this description, we will sometimes use the terms assert and negate when referring to the rendering of a signal, signal flag, status bit, or similar apparatus into its logically true or logically false state, respectively, and the term toggle to indicate the logical inversion of a signal from one logical state to the other. Alternatively, we may refer to the mutually exclusive Boolean states as logic_0 and logic_1. Of course, as is well known, consistent system operation can be obtained by reversing the logic sense of all such signals, such that signals described herein as logically true become logically false and vice versa. Furthermore, it is of no relevance in such systems which specific voltage levels are selected to represent each of the logic states.

[0005] In accordance with our prior invention previously disclosed in the Related References, the amplitude modulated ("AM") signal broadcast by the reader in an RFID system will be electromagnetically coupled to a conventional antenna, and a portion of the current induced in a tank circuit is extracted by a regulator to provide operating power for all other circuits. Once sufficient stable power is available, the regulator will produce, e.g., a power-on-reset signal to initiate system operation. Thereafter, the method disclosed in the Related References, and the associated apparatus, dynamically varies the capacitance of a variable capacitor component of the tank circuit so as to dynamically shift the f_R of the tank circuit to better match the f_C of the received RF signal, thus obtaining maximum power transfer in the system.

[0006] In general, the invention disclosed in the Related References focused primarily on quantizing the voltage developed by the tank circuit as the primary means of matching the f_R of the tank circuit to the transmission frequency, f_C, of the received signal. However, this voltage quantization is, at best, indirectly related to received signal field strength. We submit that what is needed now is an effective and efficient method and apparatus for quantizing the received field strength as a function of induced current. It is further desirable to develop this field quantization in a form and manner that is suitable for selectively varying the input impedance of the receiver circuit to maximize received power, especially during normal system operation. Additionally, in light of the power sensitive nature of RFID systems, it is desirable to vary the input impedance with a minimum power loss.

BRIEF SUMMARY OF THE INVENTION

[0007] In accordance with the preferred embodiment of our invention, we provide a sensing system for use in an RFID system. In general, the sensing system comprises an RFID tag and an RFID reader. In one embodiment, the RFID tag comprises a tank circuit having a selectively variable impedance; and a tuning circuit adapted to dynamically vary the impedance of the tank circuit, and to develop a first quantized value representative of the impedance of said tank circuit. In one alternate embodiment, the RFID tag comprises a detector circuit adapted to develop a second quantized value as a function of a field strength of a received RF signal. In yet another embodiment, the RFID tag comprises both the tank and tuning circuit, and the detector circuit. In these embodiments, RFID reader is adapted selectively to retrieve one or both of the first and second values, and, preferably, to use the retrieved values to sense changes to an environment to which the RFID tag is exposed

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

[0008] My invention may be more fully understood by a description of certain preferred embodiments in conjunction with the attached drawings in which:

[0009] FIG. **1** illustrates, in block diagram form, an RF receiver circuit having a field strength detector constructed in accordance with an embodiment of our invention;

[0010] FIG. **2** illustrates, in block diagram form, a field strength detector circuit constructed in accordance with an embodiment of our invention;

[0011] FIG. **3** illustrates, in block schematic form, a more detailed embodiment of the field strength detector circuit shown in FIG. **2**;

[0012] FIG. **4** illustrates, in flow diagram form, the sequencing of operations in the field strength detector circuit shown in FIG. **3**;

[0013] FIG. **5** illustrates, in graph form, the response of the field strength detector circuit shown in FIG. **3** to various conditions;

[0014] FIG. **6** illustrates, in block schematic form, an RF receiver circuit constructed in accordance with another embodiment of our invention;

[0015] FIG. **7** illustrates, in flow diagram form, the sequencing of the operations in the RF receiver circuit shown in FIG. **6**;

[0016] FIG. **8** illustrates, in block schematic form, an alternative representation of the impedance represented by the antenna and the tank circuit of the exemplary RFID receiver circuit.

[0017] FIG. **9** illustrates, in block schematic form, an alternative exemplary embodiment of the field strength detector circuit shown in FIG. **3**.

[0018] FIG. **10** illustrates, in block schematic form, an alternative exemplary embodiment of the field strength detector circuit shown in FIG. **3**.

[0019] FIG. **11** illustrates, in block schematic form, an exemplary RFID sub-system containing tag and reader.

[0020] In the drawings, similar elements will be similarly numbered whenever possible. However, this practice is simply for convenience of reference and to avoid unnecessary proliferation of numbers, and is not intended to imply or suggest that our invention requires identity in either function or structure in the several embodiments.

DETAILED DESCRIPTION OF THE INVENTION

[0021] Shown in FIG. **1** is an RF receiver circuit **10** suitable for use in an RFID application. As we have described in our Related References, an RF signal electromagnetically coupled to an antenna **12** is received via a tank circuit **14**, the response frequency, f_R, of which is dynamically varied by a tuner **16** to better match the transmission frequency, f_C, of the received RF signal, thus obtaining a maximum power transfer. In particular, as further noted in the Related Applications, the RMS voltage induced across the tank circuit **14** by the received RF signal is quantized by tuner **16** and the developed quantization employed to control the impedance of the tank circuit **14**. As also described in the Related References, the unregulated, AC current induced in the tank circuit **14** by the received RF signal is conditioned by a regulator **18** to provide regulated DC operating power to the receiver circuit **10**. In accordance with our present invention, we now provide a field strength detector **20**, also known as a power detector, adapted to develop a field-strength value as a function of the field strength of the received RF signal. As we have indicated in FIG. **1**, our field strength detector **20** is adapted to cooperate with the regulator **18** in the development of the field-strength value. As we shall disclose below, if desired, our field strength detector **20** can be adapted to cooperate with the tuner **16** in controlling the operating characteristics of the tank circuit **14**.

[0022] Shown by way of example in FIG. **2** is one possible embodiment of our field strength or power detector **20**. In this embodiment, we have chosen to employ a shunt-type regulator **18** so that, during normal operation, we can use the shunted 'excess' current as a reference against which we develop the field-strength value. In this regard, we use a reference **22** first to develop a shunt current reference value proportional to the shunted current, and then to develop a mirrored current reference value as a function of both the shunted current and a field strength reference current provided by a digitally-controlled current source **24**. Preferably, once the tuner **16** has completed its initial operating sequence, whereby the f_R of the tank circuit **14** has been substantially matched to the f_C of the received signal, we then enable a digital control **26** to initiate operation of the current source **24** at a predetermined, digitally-established minimum field strength reference current. After a predetermined period of time, control **26** captures the mirrored current reference value provided by the current reference **22**, compares the captured signal against a predetermined threshold value, and, if the comparison indicates that the field strength reference current is insufficient, increases, in accordance with a predetermined sequence of digital-controlled increments, the field strength reference current; upon the comparison indicating that the field strength reference current is sufficient, control **26** will, at least temporarily, cease operation.

[0023] In accordance with our invention, the digital field-strength value developed by control **26** to control the field strength current source **24** is a function of the current induced in the tank circuit **14** by the received RF signal. Once developed, this digital field-strength value can be employed in various ways. For example, it can be selectively transmitted by the RFID device (using conventional means) back to the reader (not shown) for reference purposes. Such a transaction can be either on-demand or periodic depending on system requirements. Imagine for a moment an application wherein a plurality of RFID tag devices are distributed, perhaps randomly, throughout a restricted, 3-dimensional space, e.g., a loaded pallet. Imagine also that the reader is programmed to query, at an initial field strength, all tags "in bulk" and to command all tags that have developed a field-strength value greater than a respective field-strength value to remain silent'. By performing a sequence of such operations, each at an increasing field strength, the reader will, ultimately, be able to isolate and distinguish those tags most deeply embedded within the space; once these 'core' tags have been read, a reverse sequence can be performed to isolate and distinguish all tags within respective, concentric 'shells' comprising the space of interest. Although, in all likelihood, these shells will not be regular in either shape or relative volume, the analogy should still be apt.

[0024] In FIG. **3**, we have illustrated one possible embodiment of our field strength detector **20***a*. In general, we have chosen to use a shunt circuit **18***a* to develop a substantially constant operating voltage level across supply node **28** and ground node **30**. Shunt regulators of this type are well known in the art, and typically use zener diodes, avalanche breakdown diodes, diode-connected MOS devices, and the like.

[0025] As can be seen, we have chosen to implement current reference **22** in the form of a current mirror circuit **22***a*, connected in series with shunt circuit **18***a* between nodes **28** and **30**. As is typical, current mirror circuit **22***a* comprises a diode-connected reference transistor **32** and a mirror transistor **34**. If desired, a more sophisticated circuit such as a Widlar current source may be used rather than this basic two-transistor configuration. For convenience of reference, we have designated the current shunted by shunt circuit **18***a* via reference transistor **32** as i_R; similarly, we have designated the current flowing through mirror transistor **34** as i_R/N, wherein, as is known, N is the ratio of the widths of reference transistor **32** and mirror transistor **34**.

[0026] We have chosen to implement the field strength current source **24** as a set of n individual current sources **24***a*, each connected in parallel between the supply node **28** and the mirror transistor **34**. In general, field strength current source **24***a* is adapted to source current at a level corresponding to an n-bit digital control value developed by a counter **38**. In the illustrated embodiment wherein n=5, field strength current source **24***a* is potentially capable of sourcing thirty-two distinct reference current levels. We propose that the initial, minimum reference current level be selected so as to be less than the current carrying capacity of the mirror transistor **34** when the shunt circuit **18***a* first begins to shunt excess induced current through reference transistor **32**; that the maximum reference current level be selected so as to be greater than the current carrying capacity of the mirror transistor **34** when the shunt circuit **18***a* is shunting a maximum anticipated amount of excess induced current; and that the intermediate reference current levels be distributed relatively evenly between the minimum and maximum levels. Of course, alternate schemes may be practicable, and, perhaps, desirable depending on system requirements.

[0027] Within control **26***a*, a conventional analog-to-digital converter ("ADC") **40**, having its input connected to a sensing node **36**, provides a digital output indicative of the field strength reference voltage, v_R, developed on sensing node **36**. In one embodiment, ADC **40** may comprise a comparator circuit adapted to switch from a logic_0 state to a logic_1 when sufficient current is sourced by field strength current source **24***a* to raise the voltage on sensing node **36** above a predetermined reference voltage threshold, v_{th}. Alternatively, ADC **40** may be implemented as a multi-bit ADC capable of providing higher precision regarding the specific voltage developed on sensing node **36**, depending on the requirements of the system. Sufficient current may be characterized as that current sourced by the field strength current source **24***a* or sunk by mirror transistor **34** such that the voltage on sensing node **36** is altered substantially above or below a predetermined reference voltage threshold, v_{th}. In the exemplary case of a simple CMOS inverter, v_{th} is, in its simplest form, one-half of the supply voltage (VDD/2). Those skilled in the art will appreciate that v_{th} may by appropriately modified by altering the widths and lengths of the devices of which the inverter is comprised. In the exemplary case a multi-bit ADC, v_{th} may be established by design depending on the system requirements and furthermore, may be programmable by the system.

[0028] In the illustrated embodiment, a latch **42** captures the output state of ADC **40** in response to control signals provided by a clock/control circuit **44**. If the captured state is logic_0, the clock/control circuit **44** will change counter **38** to change the reference current being sourced by field strength current source **24***a*; otherwise clock/control circuit **44** will, at least temporarily, cease operation. However, notwithstanding, the digital field-strength value developed by counter **38** is available for any appropriate use, as discussed above.

[0029] By way of example, we have illustrated in FIG. **4** one possible general operational flow of our field strength detector **20***a*. Upon activation, counter **38** is set to its initial digital field-strength value (step **48**), thereby enabling field strength current source **24***a* to initiate reference current sourcing at the selected level. After an appropriate settling time, the field strength reference voltage, v_R, developed on sensing node **36** and digitized by ADC **40** is captured in latch **42** (step **50**). If the captured field strength reference voltage, v_R, is less than (or equal to) the predetermined reference threshold voltage, v_{th}, clock/control **44** will change counter **38** (step **54**). This process will repeat, changing the reference current sourced by field strength current source **24***a* until the captured field strength reference voltage, v_R, is greater than the predetermined reference threshold voltage, v_{th}, (at step **52**), at which time the process will stop (step **56**). As illustrated, this sweep process can be selectively reactivated as required, beginning each time at either the initial field-strength value or some other selected value within the possible range of values as desired.

[0030] The graph illustrated in FIG. **5** depicts several plots of the voltage developed on sensing node **36** as the field strength detector circuit **20***a* sweeps the value of counter **38** according to the flow illustrated in FIG. **4**. As an example, note that the curve labeled "A" in FIG. **5** begins at a logic_0 value when the value of counter **38** is at a minimum value such as "1" as an exemplary value. Subsequent loops though the sweep loop gradually increase the field strength reference voltage on sensing node **36** until counter **38** reaches a value of "4" as an example. At this point, the "A" plot in FIG. **5** switches from a logic_0 value to a logic_1 value, indicating that the field strength reference voltage, v_R, on sensing node **36** has exceeded the predetermined reference threshold voltage, v_{th}. Other curves labeled "B" through "D" depict incremental increases of reference currents, i_R, flowing through reference device **32**, resulting in correspondingly higher mirrored currents flowing through mirror device **34**. This incrementally higher mirror current requires field strength current source **24** to source a higher current level which in turn corresponds to higher values in counter **38**. Thus, it is clear that our invention is adapted to effectively and efficiently develop a digital representation of the current flowing through sensing node **36** that is suitable for any appropriate use.

[0031] One such use, as discussed earlier, of our field strength detector **20** is to cooperate with tuner **16** in controlling the operating characteristics of the tank circuit **14**. FIG. **6** illustrates one possible embodiment where receiver circuit **10***a* uses a field strength detector **20***b* specially adapted to share with tuner **16***a* the control of the tank circuit **14**. In our Related References we have disclosed methods, and related apparatus, for dynamically tuning, via tuner **16***a*, the tank circuit **14** so as to dynamically shift the f_R of the tank circuit **14** to better match the f_C of the received RF signal at antenna **12**. By way of example, we have shown in FIG. **6** how the embodiment shown in FIG. 3 of our Related patent may be easily modified by adding to tuner **16***a* a multiplexer **58** to facilitate shared access to the tuner control apparatus. Shown in FIG. **7** is the operational flow (similar to that illustrated in FIG. 4 in our Related patent) of our new field strength detector **20***b* upon assuming control of tank circuit **14**.

[0032] In context of this particular use, once tuner **16***a* has completed its initial operating sequences as fully described in our Related patent, and our field strength detector **20***b* has performed an initial sweep (as described above and illustrated in FIG. **4**) and saved in a differentiator **60** a base-line field-strength value developed in counter **38**, clock/control **44** commands multiplexer **58** to transfer control of the tank circuit **16***a* to field strength detector **20***b* (all comprising step **62** in FIG. **7**). Upon completing a second current sweep, differentiator **60** will save the then-current field-strength value developed in the counter **38** (step **64**). Thereafter, differentiator **60** will determine the polarity of the change of the previously saved field-strength value with respect to the then-current field-strength value developed in counter **38** (step **66**). If the polarity is negative (step **68**), indicating that the current field-strength value is lower than the previously-saved field-strength value, differentiator **60** will assert a change direction signal; otherwise, differentiator **60** will negate the change direction signal (step **70**). In response, the shared components in tuner **16***a* downstream of the multiplexer **58** will change the tuning characteristics of tank circuit **14** (step **72**) (as fully described in our Related References). Now, looping back (to step **64**), the resulting change of field strength, as quantized is the digital field-strength value developed in counter **38** during the next sweep (step **64**), will be detected and, if higher, will result in a further shift in the f_R of the tank circuit **14** in the selected direction or, if lower, will result in a change of direction (step **70**). Accordingly, over a number of such 'seek' cycles, our invention will selectively allow the receiver **10***a* to maximize received field strength even if, as a result of unusual factors, the f_R of the tank circuit **14** may not be precisely matched to the f_C of the received RF signal, i.e., the reactance of the antenna is closely matched with the reactance of the tank circuit, thus achieving maximum power transfer. In an alternative embodiment, it would be unnecessary for tuner **16***a* to perform an initial operating sequence as fully described in our Related patent. Rather, field strength detector **20***b* may be used exclusively to perform both the initial tuning of the receiver circuit **10***a* as well as the subsequent field strength detection. Note that the source impedance of antenna **12** and load impedance of tank circuit **14** may be represented alternatively in schematic form as in FIG. **8**, wherein antenna **12** is represented as equivalent source resistance R_S **74** and equivalent source reactance X_S **76**, and tank circuit **14** is represented as equivalent load resistance R_L **78** and equivalent, variable load reactance X_L **80**.

[0033] In FIG. **9**, we have illustrated an alternate embodiment of our field strength detector illustrated in FIG. **3**. Here, as before, shunt circuit **18***b* is used to develop a substantially constant operating voltage level across supply node **28** and ground node **30**. Also, as before, the current reference **22** is implemented as a current mirror circuit **22***b* connected in series with shunt circuit **18***b* between nodes **28** and **30**. However, in this embodiment, the field strength current source comprises a resistive component **84** adapted to function as a static resistive pull-up device. Many possible implementations exist besides a basic resistor, such as a long channel length transistor, and those skilled in the art will appreciate the various implementations that are available to accomplish analogous functionality. The field strength voltage reference v_R developed on sensing node **36** will be drawn to a state near the supply voltage when the mirrored current flowing though transistor **34** is relatively small, e.g. close to zero amps, indicating a weak field strength. As the field strength increases, the current flowing through mirror transistor **34** will increase, and the field strength voltage reference v_R developed on sensing node **36** will drop proportionally to the mirrored current flowing through mirror transistor **34** as i_R/N. ADC **40**, having its input connected to sensing node **36**, provides a digital output indicative of the field strength reference voltage, v_R, developed on sensing node **36**, as described previously.

[0034] In this alternate embodiment, latch **42** captures the output state of ADC **40** in response to control signals provided by a clock/control circuit **44**. As disclosed earlier, the ADC **40** may comprise a comparator circuit. In this instance, ADC **40** is adapted to switch from a logic_1 state to a logic_0 when sufficient current is sunk by mirror transistor **34** to lower the voltage on sensing node **36** below a predetermined reference voltage threshold, v_{th}. Alternatively, ADC **40** may be implemented as a multi-bit ADC capable of providing higher precision regarding the specific voltage developed on sensing node **36**, depending on the requirements of the system.

[0035] Comparator **82** subsequently compares the captured output state held in latch **42** with a value held in counter **38** that is selectively controlled by clock/control circuit **44**. In response to the output generated by comparator **82**, clock/control circuit **44** may selectively change the value held in counter **38** to be one of a higher value or a lower value, depending on the algorithm employed. Depending upon the implementation of counter **38** and comparator **82**, clock/control circuit **44** may also selectively reset the value of counter **38** or comparator **82** or both. The digital field-strength value developed by counter **38** is available for any appropriate use, as discussed above.

[0036] In FIG. **10**, we have illustrated another alternate embodiment of our field strength detector illustrated in FIG. **3**. Here, as before, shunt circuit **18***c* is used to develop a substantially constant operating voltage level across supply node **28** and ground node **30**. In this embodiment, the current reference **22** is implemented as a resistive component **86** that functions as a static pull-down device. Many possible implementations exist besides a basic resistor, such as a long channel length transistor and those skilled in the art will appreciate the various implementations that are available to accomplish analogous functionality. The field strength voltage reference v_R developed on sensing node **36** will be drawn to a state near the ground node when the current flowing though shunt circuit **18***c* is relatively small, e.g., close to zero amps, indicating a weak field strength. As the field strength increase, the current flowing through shunt circuit **18***c* will increase, and the field strength voltage reference v_R developed on sensing node **36** will rise proportionally to the current flowing through shunt circuit **18***c*. ADC **40**, having its input connected to a sensing node **36**, provides a digital output indicative of the field strength reference voltage, v_R, developed on sensing node **36**, as described previously.

[0037] In this alternate embodiment, latch **42** captures the output state of ADC **40** in response to control signals provided by a clock/control circuit **44**. As disclosed earlier, the ADC **40** may comprise a comparator circuit. In this instance, ADC **40** is adapted to switch from a logic_0 state to a logic_1 when sufficient current is sourced by shunt circuit **18***c* to raise the voltage on sensing node **36** above a predetermined reference voltage threshold, v_{th}. Alternatively, ADC **40** may be implemented as a multi-bit ADC capable of providing higher precision regarding the specific voltage developed on sensing node **36**, depending on the requirements of the system.

[0038] Comparator **82** subsequently compares the captured output state held in latch **42** with a value held in counter **38** that is selectively controlled by clock/control circuit **44**. In response to the output generated by comparator **82**, clock/control circuit **44** may selectively change the value held in counter **38** to be one of a higher value or a lower value, depending on the algorithm employed. Depending upon the implementation of counter **38** and comparator **82**, clock/control circuit **44** may also selectively reset the value of counter **38** or comparator **82** or both. The digital field-strength value developed by counter **38** is available for any appropriate use, as discussed above.

[0039] In another embodiment, our invention may be adapted to sense the environment to which a tag is exposed, as well as sensing changes to that same environment. As disclosed in our Related References, the auto-tuning capability of tuner **16** acting in conjunction with tank circuit **14** detects antenna impedance changes. These impedance changes may be a function of environmental factors such as proximity to interfering substances, e.g., metals or liquids, as well as a function of a reader or receiver antenna orientation. Likewise, as disclosed herein, our field strength (i.e., received power) detector **20** may be used to detect changes in received power (i.e., field strength) as a function of, for example, power emitted by the reader, distance between tag and reader, physical characteristics of materials or elements in the immediate vicinity of the tag and reader, or the like. Sensing the environment or, at least, changes to the environment is accomplished using one or both of these capabilities.

[0040] As an example, the tag **88** of FIG. **11**, contains both a source tag antenna **12** (not shown, but see, e.g., FIG. **6**) and a corresponding load chip tank circuit **14** (not shown, but see, e.g., FIG. **6**). Each contains both resistive and reactive elements as discussed previously (see, e.g., FIG. **8**). A tag **88** containing such a tank circuit **14** mounted on a metallic surface will exhibit antenna impedance that is dramatically different than the same tag **88** in free space or mounted on a container of liquid. Table 1 displays exemplary values for impedance variations in both antenna source resistance **74** as well as antenna source reactance **76** as a function of frequency as well as environmental effects at an exemplary frequency:

TABLE 1

Antenna Impedance Variations			
In Free Air	860 MHz	910 MHz	960 MHz
R_s	1.9	2.5	3.7
X_s	124	136	149
@910 MHz	Free Air	On Water	On Metal
R_s	2.5	26	1.9
X_s	136	136	27

[0041] The tuner circuit **16** of our invention as disclosed in the Related References automatically adjusts the load impendence by adjusting load reactance **80** (see, e.g., FIG. **8**) to match source antenna impedance represented by source resistance **74** (see, e.g., FIG. **8**) and source reactance **76** (see, e.g., FIG. **8**). As previously disclosed, matching of the chip load impedance and antenna source impedance can be performed automatically in order to achieve maximum power transfer between the antenna and the chip. My invention as disclosed in the Related References contained a digital shift register **90** for selectively changing the value of the load reactive component, in the present case a variable capacitor, until power transfer is maximized. This digital value of the matched impendence may be used either internally by the tag **88**, or read and used by the reader **92**, to discern relative environmental information to which the tag **88** is exposed. For example, tag **88** may contain a calibrated look-up-table within the clock/control circuit **44** which may be accessed to determine the relevant environmental information. Likewise, a RFID reader **92** may issue commands (see transaction **1** in FIG. **11**) to retrieve (see transaction **2** in FIG. **11**) the values contained in digital shift register **90** via conventional means, and use that retrieved information to evaluate the environment to which tag **88** is exposed. The evaluation could be as simple as referencing fixed data in memory that has already been stored and calibrated, or as complex as a software application running on the reader or its connected systems for performing interpretive evaluations.

[0042] Likewise, consider a tag **88** containing our field strength (i.e., received power) detector **20** (not shown, but, e.g., see FIG. **6**) wherein the method of operation of the system containing the tag **88** calls for our field strength detector **20** to selectively perform its sweep function and developing the quantized digital representation of the current via the method discussed earlier. As illustrated in FIG. **11**, counter **38** will contain the digital representation developed by our field strength detector **20** of the RF signal induced current, and may be used either internally by the tag **88**, or read and used by the reader **92**, to discern relative environmental information to which the tag **88** is exposed. For example, reader **92** may issue a command to the tag **88** (see transaction **1** in FIG. **11**) to activate tuner **16** and/or detector **20** and, subsequent to the respective operations of tuner **16** and/or detector **20**, receive (see transaction **2** in FIG. **11**) the digital representations of either the matched impedance or the maximum current developed during those operations. Once again, this digital value of the field strength stored in the counter **38** may be used either internally by the tag **88**, or read and used by the reader **92**, to discern relative environmental information to which the tag **88** is exposed. For example, tag **88** may contain a calibrated look-up-table within the clock and control block **44** which may be accessed to determine the relevant environmental information. Likewise, a RFID reader may issue commands to retrieve the values contained in digital shift register **90**, and use that retrieved information to evaluate the environment to which tag **88** is exposed. The evaluation could be as simple as referencing fixed data in memory that has already been stored and calibrated, or as complex as a software application running on the reader or its connected systems for performing interpretive evaluations. Thus, the combining of the technologies enables a user to sense the environment to which a tag **88** is exposed as well as sense changes to that same environment.

[0043] Thus, it is apparent that we have provided an effective and efficient method and apparatus for quantizing the received RF field strength as a function of induced current. We have developed this field quantization in a form and manner that is suitable for selectively varying the impedance of the tank circuit to maximize received power, especially during normal system operation. Those skilled in the art will recognize that modifications and variations can be made without departing from the spirit of our invention.

Therefore, we intend that our invention encompass all such variations and modifications as fall within the scope of the appended claims.

What is claimed is:

1. A radio frequency (RF) circuit comprises:

an antenna operably coupled to receive an RF signal;

a power harvesting circuit operable to generate a first power source from the RF signal;

a tank circuit coupled to the antenna, wherein the tank circuit includes a selectively variable impedance; and

a tuning circuit operable to dynamically vary the selectively variable impedance of the tank circuit based on resonance of the RF circuit and frequency of the RF signal to substantially align the resonance of the RF circuit with the frequency of the RF signal, wherein, when the resonance of the RF circuit is substantially aligned with the frequency of the RF signal, the power harvesting circuit generates a second power source from the RF signal, wherein the second power source is greater than the first power source.

2. The RF circuit of claim **1** further comprises:

a processing module operable to generate a digital value representative of dynamic variance of the selectively variable impedance of the tank circuit;

memory operable coupled to the processing module; and

a transmitter section operable to transmit an outbound RF signal to a reader, wherein the outbound RF signal includes the digital value.

3. The RF circuit of claim **2** further comprises:

the antenna operable to receive a second RF signal, wherein the second RF signal has an adjusted transmit power with respect to the RF signal based on an interpretation of the digital value such that the second power source is at least one of a desired voltage level and a desired current level.

4. The RF circuit of claim **1**, wherein the tank circuit comprises:

an inductor; and

a variable capacitor coupled to the inductor, wherein the tuning circuit is operable to adjust capacitance of the variable capacitor such that a resonant frequency of the tank circuit substantially matches a frequency of the RF signal.

5. The RF circuit of claim **1**, wherein the power harvesting circuit comprises:

a regulator coupled to the tank circuit, wherein a current is induced in the tank circuit from the received RF signal, wherein the regulator is operable to extract a portion of the induced current to provide direct current (DC) operating power to the RF circuit.

6. The RF circuit of claim **1** further comprises:

a sensing circuit that includes:

the tank circuit having the selectively variable impedance;

the tuning circuit operable to dynamically vary the impedance of the tank circuit, and to develop a first quantized value representative of the impedance of the tank circuit; and

a detector circuit operable to develop a second quantized value as a function of a field strength of a received RF signal; and

memory, wherein the memory stores the first and second quantized values; and

a control circuit operable selectively to retrieve the first and second quantized values from the memory, wherein the retrieved first and second quantized values are used to sense changes to an environment to which the RF circuit is exposed.

7. The RF circuit of claim **6**, wherein the environment includes one or more of:

free space;

air;

liquids; and

metals.

8. The RF circuit of claim **1**, wherein the selectively variable impedance is set to an initial value.

(57) **ABSTRACT**

An antenna apparatus for harvesting ambient radio frequency, RF, energy, comprises one or more RF antenna components arranged to receive RF energy. The antenna components comprise a plurality of frequency filtering components, each filtering a respective frequency band of the received RF energy. A rectifying circuit is arranged to convert a variable electrical signal received at an input from an associated antenna, into a direct current electrical signal for supplying to an electrical energy storage unit. A power management module has an input arranged to receive the direct current and control supply of the direct current to the electrical energy storage unit. The rectifying circuit comprises a plurality of transmission lines, and the input of the rectifying circuit and the input of the power management module are connected via the transmission lines. The power management module is arranged at least partially within a boundary defined by the transmission lines.

RF ENERGY HARVESTER

RELATED APPLICATIONS

[0001] This application is a continuation of U.S. patent application Ser. No. 14/909,862, entitled "RF Energy Harvester" and filed Feb. 3, 2016. U.S. application Ser. No. 14/909,862 claims priority to PCT/GB2014/052431, entitled "RF Energy Harvester" and filed Aug. 8, 2014, which in turn claims priority to UK Patent Application No. 1314307.8, entitled "RF Energy Harvester" and filed Aug. 9, 2013. The contents of all of these applications are hereby incorporated by reference in their entireties.

FIELD OF INVENTION

[0002] This disclosure relates to an apparatus for harvesting RF energy. More specifically, but not exclusively, an antenna for receiving ambient RF energy is disclosed. In addition, a rectifier forming part of an RF energy harvesting system and the integration of the rectifier with a power management module is disclosed.

BACKGROUND TO THE INVENTION

[0003] Many electrical devices, particularly portable or remote electrical devices are powered by batteries. Batteries usually require recharging or replacing on a regular basis for continued operation of the electrical device. However, it is not always desirable or possible to connect a device to a mains power supply for recharging, or easy to gain access to the device for replacing the batteries. Moreover, it may not be possible to rely on a battery to perform with 100% reliability over extended periods and/or extreme operational/environmental conditions. As such, other means for powering/charging devices have been explored.

[0004] One proposal for obtaining electrical energy for electrical devices is by means of energy harvesting at the electrical device. Energy harvesting involves converting energy from clean, freely available sources into electrical energy and represents an environmentally friendly solution. Commonly used free energy solutions for powering electrical devices include solar, thermal and vibrational energy sources. For example, practical solar harvesters, such as solar panels and solar rectennas, utilize photovoltaic cells to convert photons into electrical energy via the photovoltaic effect. However, solutions such as solar harvesters are not appropriate for many types of remote electrical devices and are also not ideal for use in many geographical locations.

[0005] An alternative proposal is the wireless delivery of electrical power. For example, high power RF sources can be used to deliver RF power in a specific frequency band to recipient devices. The recipient devices then receive the RF energy and convert it into an electrical form, which can be used to power the device. Such systems can work efficiently in certain environments. However, such systems rely upon the presence of high energy RF transmitters, which reduces the overall attractiveness of such systems due to the need to install infrastructure, and therefore limits the number of possible applications that can use such technology.

[0006] Due to the expanse in the mobile telecommunications industry in recent decades and the corresponding increase in ambient RF energy, some research has looked at whether such ambient RF energy could be harvested. Presently, few practical energy collection solution for harvesting ambient RF energy have been reported, despite the abundance of such energy. One of the key challenges in respect of harvesting RF energy includes the collection of very low RF power, which can be as low as 10 nW. At present, RF energy harvesting does not look to be a viable option.

[0007] There is therefore still a requirement for alternative sources of power for remote devices.

SUMMARY OF INVENTION

[0008] In accordance with an aspect of the invention there is provided an antenna apparatus for use in harvesting ambient radio frequency, RF, energy. The apparatus comprises one or more RF antenna components arranged to receive RF energy for producing electricity. The one or more RF antenna components comprise a plurality of frequency filtering components, each frequency filtering component being arranged to filter a respective frequency band of the received RF energy.

[0009] The frequency filtering components may form part of the one or more RF antenna components. The frequency filtering components may be features formed in or on the one or more RF antenna components. Filtering characteristics of the features may be determined according to the dimensions of the features. The features may be formed in or on the one or more RF antenna components at positions associated with one or more resonant frequencies of the one or more RF antennas within which they are formed.

[0010] The respective frequency bands that the plurality of frequency filtering components are arranged to filter may be one or more known electromagnetic radiation frequency bands. The one or more known electromagnetic radiation frequency bands may include one or more of GSM900, GSM1800, 3G, and 4G.

[0011] One of the one or more RF antenna components may be a circular radiating patch arranged to receive a first frequency range. A first of the plurality of frequency filtering components may be a curved feature formed concentrically in or on the circular radiating patch. The first filtering component may be arranged for filtering one or more frequencies within the first frequency range.

[0012] The first frequency filtering component may be positioned at a distance from the centre of the circular radiating patch of between $\lambda_g/12$ and $\lambda_g/16$, between $\lambda_g/6$ and $\lambda_g/15$ in length, and between $\lambda_g/18.5$ to $\lambda_g/24.2$ in width, wherein λ_g is a wavelength at a centre frequency of the respective frequency band associated with the respective frequency filtering component.

[0013] A second of the plurality of frequency filtering components may be a curved feature formed concentrically in or on the circular radiating patch arranged for filtering one or more frequencies within the first frequency range. The one or more frequencies filtered by the second frequency filtering component may differ to the one or more frequencies filtered by the first frequency filtering component.

[0014] The second frequency filtering component may be positioned at a distance from the centre of the circular radiating patch of between $\lambda_g/12$ to $\lambda_g/24$, between $\lambda_g/4.5$ to $\lambda_g/5.7$ in length, and between $\lambda_g/18.5$ to $\lambda_g/24.2$ in width.

[0015] One of the one or more RF antenna components may be a ground plane arranged to define the radiation pattern of the antenna.

[0016] One of the plurality of frequency filtering components may be a feature formed in or on the ground plane for filtering one or more frequencies within the second frequency range. The feature formed in or on the ground plane may be U-shaped.

[0017] The feature formed in or on the ground plane may be at a distance from a nearest edge of the circular radiating patch of between $\lambda_g/5.4$ to $\lambda_g/8.1$, between $\lambda_g/7.4$ to $\lambda_g/10.5$ in length, and between $\lambda_g/15.2$ to $\lambda_g/24.2$ in width.

[0018] The RF antenna arrangement may comprise a substrate on which the circular radiating patch and the ground plane are formed. The RF antenna arrangement may comprise a connection portion at one edge of the substrate for connecting the circular radiating patch and the ground plane to a harvesting circuit. The circular radiating patch may join the connection portion via an elongate feed-line. A length of the elongate feed-line may be set so that a distance between the circular radiating patch and the ground plane defines an output impedance of the antenna. The distance between the circular radiating patch and the ground plane may be $\lambda_g/4.8$. The substrate may be flexible.

[0019] The plurality of frequency filtering components may be one or more of notches, grooves, or protrusions.

[0020] In accordance with another aspect of the invention there is provided apparatus comprising a rectifying circuit arranged to convert a variable electrical signal received at an input from an associated antenna into a direct current electrical signal for supplying to an electrical energy storage unit, the antenna for use in harvesting ambient radio frequency, RF, energy. The apparatus also comprises a power management module having an input arranged to receive the direct current and control supply of the direct current to the electrical energy storage unit. The rectifying circuit comprises a plurality of transmission lines, wherein the input of the rectifying circuit and the input of the power management module are connected via the plurality of transmission lines. The power management module is arranged at least partially within a boundary defined by the plurality of transmission lines.

[0021] The plurality of transmission lines may form first and second arms. The first arm may connect the input of the rectifying circuit to the input of the power management module via a forward biased rectifying device. The second arm may connect the input of the rectifying circuit to the input of the power management module via a reverse biased rectifying device. The first arm may comprise a first transmission line that connects the input of the rectifying circuit to the forward biased rectifying device, and a second transmission line that connects the forward biased rectifying device to the input of the power management module. The first transmission line may be arranged for impedance matching the rectifier to the associated antenna, and the second transmission line may be arranged for impedance matching the rectifying circuit with the power management module. The first transmission line may have a length of between $\lambda_g/6.8$ and $\lambda_g/8.1$, wherein λ_g is a wavelength at a centre frequency of a respective frequency band arranged to be received by the associated antenna. A filtering circuit may be connected to the second transmission line. The filtering circuit may be a quarter wavelength stub.

[0022] The second transmission line may comprise a linking transmission line and an impedance matching transmission line. The linking transmission line may be arranged between the rectifying device and the filtering circuit. The linking transmission line is arranged to absorb a capacitive reactance associated with the rectifying device. The impedance matching transmission line may be arranged between the filtering circuit and the power management module. The linking transmission line may have a length of between $\lambda_g/4.3$ and $\lambda_g/5.6$. The impedance matching transmission line may have a length of between $\lambda_g/3.8$ and $\lambda_g/4.4$.

[0023] The power management module may be arranged within the rectifying apparatus with the following characteristics. The power management module may be connected at a first end to the output of the rectifying circuit. A distance between a second end of the power management module and the input of the rectifying circuit may be set to be between $\lambda g/2.5$ and $\lambda g/5$. A distance between a first side of the power management module may be set at between $\lambda g/6.5$ and $\lambda g/12$ from an edge of the first arm. A distance between a second side of the power management module may be set at between $\lambda g/9$ and $\lambda g/16.4$ from an edge of the second arm.

[0024] In accordance with a further aspect of the invention there is provided an RF energy harvesting system, comprising an antenna as described herein and an apparatus as described herein. The RF energy harvesting system may further comprise an electrical energy storage unit arranged to receive and store electrical energy from the power management module of the apparatus.

[0025] A rectenna for harvesting ambient RF energy at power levels below 3 μW is disclosed. The rectenna may comprise an ultra-wide band planer monopole antenna operational over the GSM900, GSM1800 and 3G RF frequency bands. The rectenna may also comprise a full-wave rectifier having a differential voltage output and operational input powers below 3 μW.

[0026] An ambient RF harvester is presented where efficiencies above 45% are achievable at input RF power levels below 3 μW. To achieve this efficiency, a single multiband antenna and a full-wave detector may be provided. Such a harvester not only charges an energy storage unit faster, but is capable of operating in more locations and/or with more flexibility in spatial orientation.

[0027] A full-wave rectifier is disclosed with differential output and a modified omnidirectional disc monopole antenna with harmonic rejection filters. The new harvester design may be capable of operating with an efficiency of 45% in locations with lower available RF power.

[0028] A tri-band RF energy harvester is disclosed with an UWB antenna and integrated harmonic band rejection. A tetra or N-element harvester array may be provided.

[0029] Advantageously, a harvester is provided that is capable of providing duty cycles higher than 11% for applications requiring up to 1 mW.

[0030] A harvester that avoids harmonic re-radiation thereby improving efficiency and minimizing detection is disclosed. The harvester may achieve this by filtering the higher order harmonics such that they are not radiated by the antenna. Consequently, it is difficult for a dedicated receiver to detect the presence of the harvester when covert operation is required.

[0031] In addition, a harvester that provides DC-load isolation from higher-order harmonics is disclosed. The harvester may achieve this by use of a high frequency filtering circuit. For example, quarter wavelength stubs may form part of the rectifier for performing such filtering. Such stubs act as short circuits at the fundamental frequency, thus filtering RF signal from the output. Alternatively, resonant structures such as LC tuned circuits can be used to perform such filtering functionality.

[0032] A harvester that is capable of 3rd harmonic rejection for all received bands is disclosed. Since half-wave rectification produces odd harmonics and full wave rectification produces even harmonics in the current waveform the high order harmonics may be filtered at the output by quarter wavelength stubs and by notches formed in the antenna.

[0033] The antenna may be formed on a substrate having a bend radius 10× the thickness of the antenna substrate. The minimum bend radius may be 8.6 mm. The substrate thickness may be 790 μm. The metal antenna formed on the substrate may be 35 μm thick. The metal may be formed of any suitable conductive material. For example, the metal antenna may be formed of copper. The dielectric properties of the substrate of dielectric constant ϵr may be 2.33 and loss tangent tan δ may be 0.0012.

BRIEF DESCRIPTION OF THE DRAWINGS

[0034] Exemplary embodiments of the invention shall now be described with reference to the drawings in which:

[0035] FIG. **1** illustrates an RF energy harvesting system;

[0036] FIG. **2** illustrates a single multi-band antenna used in the system of FIG. **1**;

[0037] FIG. **3** illustrates a microstrip full-wave rectifier with a differential output as used in the system of FIG. **1**;

[0038] FIG. **4** illustrates the rectifier of FIG. **4** with the PMM circuit placed inside the rectifier;

[0039] FIG. **5** illustrates an antenna conformed to the surface of a pipe; and

[0040] FIG. **6** shows an array of antennas conformed to the surface of a pipe.

[0041] Throughout the description and the drawings, like reference numerals refer to like parts.

SPECIFIC DESCRIPTION

[0042] A general overview of an RF energy harvesting system shall now be described with reference to FIG. **1**.

[0043] A rectenna **100** is shown that includes an antenna **101** arranged to receive ambient RF energy. The antenna is designed to receive ambient RF energy across a large frequency range and therefore the electrical output of the antenna **101** has a power profile that fluctuates considerably across its reception frequency range. The output of the antenna **101**, which provides a variable electrical signal, is connected to a rectifier **103** via an impedance matching network **102**. The impedance matching network **102** is provided to minimize losses due to impedance mismatch between components of the rectenna. The rectifier then converts the received time varying electrical signal into a DC electrical signal. The output of the rectifier is then smoothed and filtered in a smoothing/filtering circuit **104**. This smoothed DC energy is then fed into a power management module (PMM) **105** to provide useful regulated voltages and charge a storage unit **106**, which in this case is a storage capacitor $C_{storage}$. The transmission of current to the storage unit **106** and corresponding electrical storage in the storage unit **106** is controlled by a power management module (PMM) **105**. The PMM provides maximum power point tracking in addition to working as a boost converter. The maximum power tracking capabilities of the PMM allow the system to maximize the power transfer to the load by ensuring that the ideal load is present across a wide range of input RF power levels. Therefore, the PMM also helps to provide a good impedance match with the antenna. The PMM is also arranged to control a switch **108** that connects the electrical energy stored in the storage unit **106** to a load, which in this case is an LED for simplicity of explanation. However, in practice the PMM controls the supply of power from the storage unit **106** to the device, i.e. the load being powered.

[0044] The rectenna **100** is designed to maximize the ambient RF energy received by the antenna **101**, and minimize the losses in the conversion of the received energy to energy suitable for storing in the storage unit **106**. The various components of the rectenna **100** shall therefore now be described in detail.

[0045] In order to maximize the power harvested by the rectenna and reduce the size of the harvester, the antenna **101** is a single multi-band antenna, as can be seen in FIG. **2**.

[0046] The antenna **101** is a planar antenna structure comprising a substrate upon which the receiving components of the antenna are formed. The antenna **101** is a modified microstrip disc monopole antenna comprising receiving components including a circular-shaped radiating patch **110**, a feed line **111** and a rectangular shaped ground plane **112**. The circular-shaped radiating patch **110** and feed line **111** are arranged on one side of the substrate, and the ground plane **112** is arranged on the opposing side of the substrate. While the antenna is shown as having a microstrip-based feedline it will be appreciated that a coplanar waveguide feed is provided in alternative arrangements, or a combination of both a microstrip-based feedline and a coplanar waveguide feed. The substrate may be made of any low loss material, for example, glass, ceramic, FR4. The planar characteristics of the antenna allow it to be formed on the same substrate as the rest of the harvester system.

[0047] The antenna **101** is arranged to be substantially omnidirectional in order to maximize the received RF radiation. Furthermore, the structural components of the antenna are arranged to maximize the receipt of RF energy from different possible sources. Since most ambient RF energy comes from mobile telecommunications, the antenna **101** is arranged to operate across an ultra-wide band covering a plurality of the following bands: GSM900, GSM1800, 3G, WiFi and 4G. It will be appreciated that an alternative antenna arrangement could be arranged to receive other frequency bands, higher and lower than those mentioned above to cover radio, TV and other ISM bands, if desired. The circular-shaped radiating patch **110** is primarily arranged for receiving all bands, while the ground plane **112** is modified to enhance the 3^{rd} harmonic rejection of specific bands 3G and 4G, which is generated by the rectification process. The arrangement of the radiating patch **110** and ground plane **112** for receiving these different frequency bands shall now be discussed in detail.

[0048] The radiating patch **110** is circular in shape and positioned on an upper portion of the substrate. An elongated electrical feed line **111** in the form of a microstrip transmission line provides a connection from the circular-shaped radiating patch **110** to an end surface of the substrate at point **111***a*. It is at this point that the antenna **100** is connectable to the next stage of the energy harvesting system. The elongate track **111** not only acts to enable the remainder of the rectenna to be connected to the radiating patch **110**, but also provides impedance matching, as will be discussed. The radius of the disc is a quarter wavelength of the lowest frequency that the antenna is arranged to receive, e.g. 945 MHz for GSM900.

[0049] The ground plane **112** is rectangular in shape and extends from a bottom of the antenna substrate to a point just under half way along the length of the antenna substrate. In alternative arrangements the ground plane may take a different form. The shape of the ground plane defines the impedance and the radiation pattern. An electrical connection on an end surface of the substrate allows for the elongated track to be electrically connected to the rest of the energy harvesting system. The circular-shaped radiating patch, feedline and ground plane are formed of a conductive material such as copper.

[0050] The antenna's impedance can be modified to conjugately match that of the rectifier by varying the width of the antenna feed and the distance between the circular-shaped radiating patch and the ground plane. In particular, the distance between the bottom of the circular-shaped radiating patch **110** and the top of the ground plane **112** can be used to tune the impedance to 50Ω (or any chosen reference impedance) and optimize the desired omnidirectional pattern. The shape and overlap of the ground plane with the disc defines the radiation pattern by reflecting the field lines coming from the disc. In consequence, this also defines the gain of the antenna which can be between 2.3 and 4.8 dBi. This distance is also dependent upon the wavelengths that the antenna is arranged to receive. In practice the distance between the bottom of the circular-shaped radiating patch and the top of the ground plane is set between: –λg/20 and λg/12.5, where λg is the guided wavelength of the signal at the centre frequency of the selected frequency band. A distinction of λg and λo is used to highlight that this is the wavelength of the guided-wave structure, which is different than that in free space.

[0051] The antenna **101** has a number of frequency filtering features that are formed on the antenna and change the frequency response characteristics of the antenna. In particular, these filters are arranged to filter out the third harmonic generated by the full-wave rectifier at each one of the selected bands that the antenna is arranged to receive, e.g. GSM900, GSM1800, and 3G. When the antenna is used with a half-wave rectifier, a second harmonic filter is required, rather than a third harmonic filter.

[0052] First and second filtering notches **110*a*** and **110*b*** are provided on the circular-shaped radiating patch, while a further notch **112*a*** is provided on the ground plane **112**. The first and second notches **110*a***, **110*b*** are curved and concentrically arranged on the circular-shaped radiating patch. The first filtering notch **110*a*** has a length of λg/6 to λg/7.5. The first filtering notch is radially positioned at between λg/12 and λg/16 from the centre of the circular-shaped radiating patch. The width of the first filtering notch is between λg/18.5 and λg/24.2, which optimizes the return loss and the bandwidth of the notches. The second filtering notch **110*b*** has a length of between λg/4.5 and λg/5.7, a width of between λg/18.5 and λg/24.2, and the notch is radially positioned λg/12 to λg/24 from the centre of the circular-shaped radiating patch. By modifying the position and the width of the notches, the return loss can be increased and the bandwidth optimized to cover all of the targeted frequencies. It is the resonances generated by the position and geometry of the notches that defines the associated return loss and bandwidth of the filtering provided by the notches.

[0053] The notch **112*a*** formed in the ground plane **112** is U-shaped with the base of the U facing downwards. The centre of the notch in the ground plane **112** is between λg/5.4 to λg/8.1 from the lower edge of the circular radiating patch, and the notch **112*a*** has a length of between λg/7.4 and λg/10.5 and a width of between λg/15.2 and λg/24.2.

[0054] In summary, the length of the first and second notches is approximately a third of the wavelength of the third harmonic and the width is proportional to the bandwidth characteristics of the filter. The U-shaped **112*a*** notch is included to filter the harmonics created by the 3G rectifier Since there is a different rectifying circuit for each band, and each rectifier generates third order harmonics corresponding to their frequency of operation, different filters or notches are required for each respective component of the antenna.

[0055] In alternative arrangements additional notches can be added to the structure, especially in the circular-shaped radiating patch. Additional notches may be used if harvesting is also desired at other bandwidths, such as 4G or WiFi. However, harmonic rejection will be lower than –2 dB. In other words, the additional filters will not be able to achieve the desired filtering properties and it is possible than around 50% of the power in the harmonics will not be filtered.

[0056] FIG. **3** illustrates the rectifying circuit **103** of FIG. **1**. The rectifying circuit **103** is a microstrip full-wave rectifier with a differential output. The rectifying circuit shown in FIG. **3** includes the impedance matching **202**, rectifier **203**, and filtering **104** components shown in the schematic diagram of FIG. **1**. The rectifying circuit is designed to be as lossless as possible to thereby reduce diode voltage drops resulting of a conventional full-wave (four diode) rectifier. This is primarily achieved by ensuring that accurate impedance matching is provided throughout the circuit. The rectifier **203** is tuned to the frequency of the frequency range that it is receiving form the antenna **101**. In the case of the antenna **101**, which is arranged to receive multiple bands, multiple rectifiers **203** are provided for each respective band. However, in the Figures only a single rectifier is shown and explained for ease of explanation.

[0057] The output from the antenna **101** is received at the feed **201** of a microstrip transmission line. At this point the microstrip transmission line splits into two arms, one connecting the input of the rectifier to the output via a forward biased rectifying element **203**, and a second arm connecting the input of the rectifier to the output via a second reverse biased rectifying element **204**.

[0058] The arms of the microstrip transmission line **202** therefore extend perpendicularly left and right from the input **201**. The track width of the microstrip transmission line is set according to the desired characteristic impedance of the circuit. The track width can also be set in order to simplify the impedance matching of the rectifying circuit with the antenna. At each end of the impedance matching microstrip transmission line **202** further parallel tracks run for a short distance perpendicular to the impedance matching microstrip transmission line **202** and then each join a first terminal of a respective rectifying element **203**, **204**. The length of impedance matching microstrip transmission line **202** is set so as to match the impedance of the antenna **101**, which in this case is 50Ω. This length is preferably between λg/6.8 and λg/8.1. Hence, the impedance matching microstrip transmission line is performing the functionality of the impedance transformer **102** of FIG. **1**. The width and length of the microstrip transmission lines between the input and the rectifying elements are used to tune the input impedance of the rectifier.

[0059] The rectifying elements are Schottky diodes **203**, **204**, with the first diode **203** being forward biased and the second diode **204** being reverse biased. It will be appreciated that in alternative arrangement a transistor based rectifying arrangement may be provided, for example FETs may be modified to perform the rectification functionality.

[0060] The further microstrip transmission line then extends for another short portion **205**, **206** from a second terminal of the respective diode **203**, **204**. The length and width of this part of microstrip line is arranged to absorb the capacitive reactance of the diode because they define an inductive reactance. In addition, the length and width of this part of the microstrip line can be used in tuning the input impedance of the rectifying circuit. The length of the further microstrip transmission line **205**, **206** is preferably between λg/4.3 and λg/5.6. At this point, λ/4 stubs **207**, **208** extend perpendicularly from the ends of the microstrip transmission lines **205**, **206**. The λ/4 stubs **207**, **208** perform the filtering functionality **104** of FIG. **1**. The stubs are used to filter the fundamental harmonic from the output, providing DC at the output. The λg/4 stub ensures that the fundamental and the higher order harmonics are below −45 dBm.

[0061] The microstrip transmission line then continues past the stubs for a longer distance **209**, **210**, until the two arms of the microstrip transmission line extend perpendicularly such that they are again aligned and join at the two output terminals. This section is preferably between λg/3.8 and λg/4.4 in length. This section works as an impedance transformer so that the load and the rest of the rectifier have the conjugate match of the antennas' input impedance throughout a range of frequencies and input power levels.

[0062] In use, diode **203** rectifies the positive part of the received signal and diode **204** rectifies the negative part of the received signal. The quarter wavelength stubs filter the fundamental harmonic from the output ensuring that DC is available. Since the output connections are not grounded, the negative voltage coming from the diode **204** is the reference to the rest of the system blocks, providing a higher voltage to reach the cold-start voltage (330 mV) of the PMM.

[0063] The output is a differential output, which allows the system to provide a higher output voltage VPMM and reach the minimum voltage required by the Power Management Module (PMM), 330 mV, with input power levels below 3 μW (−25 dBm). Furthermore, by using a differential output ground vias are avoided, reducing losses, helping to achieve a better match between simulations and measurements, as well as simplifying fabrication.

[0064] A single full-wave rectifier can achieve 12% efficiency at −26 dBm of input power and up to 46% at −10 dBm. The return loss is below the −10 dB limit ensuring an almost complete cover of the selected operating band. The fractional bandwidth varies between 2 to 6.2% depending on the operating frequency. The output of the harvester for the input power range mentioned previously is between, 75 to 550 mV.

[0065] In order to minimize the footprint of the complete RF energy harvester, the PMM circuit **300** is placed inside a boundary defined by the transmission lines of the full-wave rectifier as shown in FIG. **4**. This is in contrast to known systems which place the PMM **300** in series with the rectifier outside the perimeter of the rectifier. However, careful considerations are required to avoid coupling between the rectifying structure and the miniaturized PMM circuit **300**. To minimize the electromagnetic interaction between the PMM circuit **300** and the full-wave rectifier the distance between the edge of the PMM circuit **300** and the microstrip transmission line of the rectifier are set as follows. The PMM circuit **300** joins the differential output directly. Hence, the distance between the PMM circuit **300** and the microstrip transmission line **211**, **212** joining the differential output is negligible. Then, the distance between the opposite end of the PMM circuit **300** to the one joining the differential output and the input to the rectifying circuit is set to be between λg/2.5 and λg/5. A first side of the PMM circuit **300** is set at between λg/6.5 and λg/12 from a first upper edge **210**, as well as from the second lower edge of the microstrip transmission line and the distance between the PMM **300** and the differential output is set at between λg/9 and λg/16.4.

[0066] In the arrangement shown in FIG. **4** the PMM **300** is provided substantially within the boundary defined by the transmission lines. It will be appreciated that in alternative arrangements the PMM may only be provided within some of the boundary of the transmission line, which would still provide some of the space savings the energy harvester system as a whole.

[0067] In addition to the location of the PMM circuit, the layout shown in FIG. **4** avoids the use of vias, while providing connections for the rectifier's differential output and the "grounded" PMM output.

[0068] FIG. **5** shows how the antenna, and in consequence the rectenna, can conform to surfaces. In this case, the substrate on which the antenna **100** is formed is made from a flexible material. Consequently, the antenna **100** is bent around a pipe **500**. In this conformal antenna design the pipe **500** is a PVC water pipe with the following characteristics: radius=5-10 cm, ϵr=2.88, and tan δ=0.089. There is no return loss degradation from bending the antenna around the pipe.

[0069] It will also be appreciated that in an alternative arrangement multiple antennas may be provided in an array. For example, FIG. **6** shows an array of antennas **100** conformed to a pipe **500**. Use of several rectennas increases the total harvested power. The distance between each harvester can be as close as λo/4.8, where λo is the wave-length of the antenna's first resonance.

[0070] It will be appreciated that these examples of conforming the antenna to a pipe are applicable to any cylindrical object.

[0071] It will be appreciated that alternative arrangements could be provided wherein similar notches are placed in other types of monopoles and planar antennas such as a bow-tie and a square patch. The ground plane could be extended to modify the radiation pattern of the antenna. This would also modify the gain of the antenna.

[0072] In alternative arrangements multiple filtering components are formed together as a filtering arrangement. In other words, as single filtering arrangement is provided having multiple filtering components, each filtering component arranged to perform a specific filtering functionality such as performing filtering for a specific frequency band.

[0073] It will be appreciated that the harvester described herein may be used in various applications such as for electronic paper displays, low power displays, industrial sensors (e.g. strain-gauge, temperature, pressure, inclination, flow, proximity, smoke, gases, COx, NOx), powering LEDs, and charging storage units.

[0074] Furthermore, it will be appreciated that the impedance matching network can be omitted if the port impedance of the antenna is designed to directly match that of the rectifier.

[0075] It will be appreciated that the rectifying circuit need not be a microstrip-based circuit. For example, in alternative arrangements stripline, coplanar strip or CPW guided-wave structures are used. In yet further arrangements lumped-element or lumped-distributed components are used.

[0076] In alternative arrangements the full-wave rectifier can be scaled up or down in frequency to any desired frequency band.

[0077] In alternative arrangements the antenna is at least one of a bow-tie antenna, a modified square patch antenna, dual-monopole antenna, a log-periodic antenna, a 3D antenna, or a non-planar antenna such as a helical or double-helix antenna.

[0078] It will be appreciated that other filtering features such as protrusions could achieve the same band filtering response as the notch filter described herein. Furthermore, while the notches formed in the circular radiating patch are shown as being concentric, it will be appreciated that the notches need not be concentric. However, improved performance can be achieved by use of concentric notches.

[0079] It will be appreciated that the filtering features for different bands may be provided on either side of the antenna structure. However, use of a U-notch in the ground plane achieves an improved performance for higher frequencies than for lower frequencies.

[0080] The rectenna described above is primarily described for use in harvesting ambient RF energy. However, it will be appreciated that the rectenna can also be used for receiving RF energy from a dedicated source, or for receiving some RF energy from a dedicated source as well as harvesting ambient RF energy.

[0081] The rectifier described herein is arranged for use with a single frequency band. When an antenna is arranged to receive multiple frequency bands a respective rectifier is utilized for each band.

[0082] Where components of the system are shown or described in a way that defines a particular orientation such as upper or lower, it will be appreciated that the orientation is not important but only the relative position(s) of system components.

What is claimed is:

1. An antenna apparatus (**101**) for use in harvesting ambient radio frequency, RF, energy and connectable to a rectifier (**103**), the antenna apparatus (**101**) comprising:

a substrate comprising a first side and a second side opposing the first side;

a radiating patch (**110**) formed on the first side of the substrate; and

a ground plane (**112**) formed on the second side of the substrate,

wherein the radiating patch (**110**) is arranged to receive RF energy for producing electricity,

wherein the radiating patch (**110**) comprises first and second filtering notches (**110***a*, **110***b*) each being arranged to modify a return loss and bandwidth of the antenna apparatus (**101**) with respect to a targeted frequency of the received RF energy,

wherein the ground plane (**112**) comprises a ground plane notch (**112***a*), and

wherein the ground plane notch (**112***a*) is arranged to filter harmonics created by the rectifier (**103**).

2. The antenna apparatus according to claim **1**, wherein the return loss and bandwidth of the antenna apparatus (**101**) modified by the first and second filtering notches (**110***a*, **110***b*) are determined according to the dimensions of the first and second filtering notches (**110***a*, **110***b*), and wherein the first and second filtering notches (**110***a*, **110***b*) are formed in or on the one or more RF antenna components at positions associated with one or more resonant frequencies of the radiating patch (**110**) within which they are formed.

3. The antenna apparatus according to claim **1**, wherein the targeted frequency of the received RF energy lies in one or more known electromagnetic radiation frequency bands, and wherein the one or more known electromagnetic radiation frequency bands include one or more of GSM900, GSM1800, 3G, and 4G.

4. The antenna apparatus according to claim **1**, wherein the radiating patch (**110**) is arranged to receive a first frequency range and the radiating patch (**110**) is circular-shaped.

5. The antenna apparatus according to claim **4**, wherein the first filtering notch (**110***a*) is a curved feature formed concentrically in or on the circular-shaped radiating patch (**110**), the first filtering notch (**110***a*) being arranged for filtering one or more frequencies within the first frequency range.

6. The antenna apparatus according to claim **5**, wherein the first filtering notch (**110***a*) is:

positioned at a distance from the centre of the circular-shaped radiating patch of between λg/12 and λg/16;

between λg/6 and λg/15 in length; and

between λg/18.5 to λg/24.2 in width, wherein

λg is a wavelength at a centre frequency of the respective frequency band associated with the respective filtering notch (**110***a*).

7. The antenna apparatus according to claim **5**, wherein the second filtering notch (**110***b*) is a curved feature formed concentrically in or on the circular-shaped radiating patch (**110**) arranged for filtering one or more frequencies within the first frequency range, wherein the one or more frequencies filtered by the second filtering notch (**110***b*) differ to the one or more frequencies filtered by the first filtering notch (**110***a*).

8. The antenna apparatus according to claim **6**, wherein the second filtering notch (**110***b*) is:

positioned at a distance from the centre of the circular-shaped radiating patch (**110***a*) of between λg/12 to λg/24;

between λg/4.5 to λg/5.7 in length; and

between λg/18.5 to λg/24.2 in width, wherein

λg is a wavelength at a centre frequency of the respective frequency band associated with the respective filtering notch (**110***b*).

9. The antenna apparatus according to claim **4**, wherein the ground plane is arranged to define the radiation pattern of the antenna apparatus (**101**).

10. The antenna apparatus according to claim **9**, wherein the ground plane notch (**112***a*) is for filtering one or more frequencies within a second frequency range.

11. The antenna apparatus according to claim **10**, wherein the ground plane notch (**112***a*) is U-shaped.

12. The antenna apparatus according to claim **10**, wherein the ground plane notch (**112***a*) is formed in or on the ground plane:

at a distance from a nearest edge of the circular-shaped radiating patch of between λg/5.4 to λg/8.1;

between λg/7.4 to λg/10.5 in length; and

between λg/15.2 to λg/24.2 in width, wherein λg is a wavelength at a centre frequency of the respective frequency band associated with the respective frequency filtering component.

13. The antenna apparatus according to any of claim **9**, wherein the substrate is flexible.

(57) **ABSTRACT**

A resonant transformer connected between a ground terminal and elevated terminal draws current from the earth's electric field through a primary winding of the transformer. An impulse generator applies a high voltage impulse to the primary winding of the resonant transformer to cause current to flow from the ground terminal through the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

POWER RECEIVER FOR EXTRACTING POWER FROM ELECTRIC FIELD ENERGY IN THE EARTH

[0001] This application is a continuation of U.S. application Ser. No. 16/521,764, filed Jul. 25, 2019, which is a continuation of U.S. application Ser. No. 15/397,281, filed Jan. 3, 2017, now U.S. Pat. No. 10,389,138, which is a continuation-in-part of U.S. application Ser. No. 14/509,772, filed Oct. 8, 2014, U.S. Pat. No. 9,564,268, which claims the benefit of U.S. Provisional Application No. 61/889,894, filed Oct. 11, 2013, the disclosures of each of which are incorporated by reference herein in their entirety.

TECHNICAL FIELD

[0002] The present invention relates generally to renewable energy, and more particularly to methods and apparatus for extracting energy from subsurface electrical fields beneath the earth's surface.

BACKGROUND

[0003] The earth and the ionosphere cavity may be viewed as a global electric circuit. Electrical currents are constantly flowing within the earth and its atmosphere. Within the earth, the majority of the earth's energy is carried by extremely low frequency (ELF) and ultralow frequency (ULF) waves in the 0-200 Hz frequency range. The earth's rotating magnetic field and positive lightning are two energy sources that sustain the ELF/ULF waves within the earth and the atmosphere.

[0004] A great deal of research has been devoted to studying the electric field present in the earth's ionosphere cavity. Joseph M. Crawley, the "Fair Weather Atmosphere as a Power Source", Proceedings ESA Annual Meeting on Electrostatics 2011; O. Jefimenko, "Operation of Electric Motors from Atmospheric Electric Field," American Journal of Physics, Vol. 39, Pgs. 776-779, 1971; M. L. Breuer, "Usability of Tapping Atmospheric Charge as a Power Source," Renewable Energy, Vol. 28, Pgs. 1121-1127, 2003. Numerous attempts have been made in the past to extract electrical energy from the earth's atmosphere. For example, U.S. Pat. No. 1,540,998 to Plauson describes a system for converting atmospheric electrical energy into usable power. These past attempts have been successful in producing only small amounts of power from the electrical field in the earth's ionosphere cavity. The modest success of these experiments compared to results from other renewable energy sources, such as solar and wind, has tempered further research and prevented widespread use of the electric field in the ionosphere cavity as an energy source.

SUMMARY

[0005] The present invention relates to a power receiver for extracting power from electric fields beneath the earth's surface. In embodiments of the present disclosure, a resonant transformer connected to a ground terminal draws current from the earth's electric field through the primary winding of the transformer. Current flow through the resonant transformer is induced by applying a high voltage impulse to the primary winding. The flow of current through the primary winding of the resonant transformer induces a current in the secondary winding, which may be converted and filtered to a usable form, e.g. 60 Hz AC or DC.

[0006] In some embodiments of the power receiver, the resonant frequency of the resonant transformers is below 200 Hz.

[0007] In some embodiments of the power receiver, the resonant transformer comprises a ferro-resonant transformer.

[0008] In some embodiments, the power receiver further comprises an elevated terminal.

[0009] In some embodiments of the power receiver, the primary winding of the resonant transformer is connected between the ground terminal and elevated terminal.

[0010] In some embodiments of the power receiver, the elevated terminal comprises an upper capacitive plate coupled to the earth's ionosphere cavity.

[0011] In some embodiments of the power receiver, the impulse generator comprises the upper capacitive plate and a spark gap connected between the upper capacitive plate and the primary winding of the resonant transformer. The spark gap comprises a pair of electrodes separated by a gap and configured to generate a spark when a voltage difference between the electrodes reaches a predetermined level.

[0012] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses, and a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

[0013] In some embodiments of the power receiver, the impulse generator comprises a pulse generator for generating low voltage pulses, and a step-up transformer connected to the primary winding of the resonant transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses.

[0014] In some embodiments of the power receiver, the impulse generator comprises a solid state spark generator.

[0015] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in parallel with the primary winding.

[0016] In some embodiments of the power receiver, the resonant transformer includes a capacitor connected in series with the primary winding between the impulse generator and the elevated terminal.

[0017] In some embodiments, the power receiver comprises multiple resonant transformers having primary windings connected in parallel between the ground terminal and the elevated terminal.

[0018] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0019] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0020] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0021] Another embodiment of the power receiver comprises a resonant circuit connected to a ground terminal disposed below the surface of the earth, an impulse generator for generating and applying a high voltage electrical impulse to the resonant circuit to induce current flow from the ground terminal through the resonant circuit, and a power conversion circuit connected to the resonant circuit to convert electrical current flowing through the resonant circuit to a desired form. The resonant circuit has a resonant frequency below 200 Hertz.

[0022] In some embodiments of the power receiver, the resonant circuit comprises a resonant transformer having a primary winding, a secondary winding, and resonant capacitor connected in series with the primary winding.

[0023] In some embodiments of the power receiver, the resonant circuit comprises multiple resonant transformers having primary windings connected in parallel to the ground terminal.

[0024] In some embodiments of the power receiver, the resonant transformers have different resonant frequencies.

[0025] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are all below 200 Hz.

[0026] In some embodiments of the power receiver, the resonant frequencies of the resonant transformers are matched to respective Schumann resonances.

[0027] Other embodiments of the disclosure comprise a ground terminal for a power receiver. In one embodiment, the ground terminal comprises a ground shaft configured for insertion beneath the surface of the earth, a hollow cylinder surrounding the ground shaft and having a plurality of openings, and a plurality of ground wires connected at one end to the ground shaft. The ground wires are wound around the ground shaft and have free ends protruding through respective openings in the hollow shaft so that rotation of the ground shaft relative to the hollow cylinder causes the ground wires to extend radially into the earth.

[0028] Other embodiments of the disclosure comprise methods of extracting power from the earth. In one embodiment, the method comprises applying a high voltage impulse to resonant circuit coupled to a ground terminal disposed beneath the surface of the earth to initiate resonance in the resonant circuit and induce the flow of current from the ground terminal to the resonant circuit, and converting the current flowing from the ground terminal into the resonant circuit into a useful form.

[0029] In some embodiments of the method, the resonant circuit comprises a resonant transformer including a primary winding coupled to the ground terminal and a second winding coupled to a power converter, and applying a high voltage impulse to resonant circuit comprises applying a high voltage impulse to the primary winding of the resonant transformer.

[0030] In some embodiments of the method, applying a high voltage impulse to the primary winding of the resonant transformer comprises applying an impulse in the range to 10,000 to 40,000 volts to primary winding of the transformer.

BRIEF DESCRIPTION OF THE DRAWINGS

[0031] FIG. **1** illustrates a first exemplary embodiment of a power receiver.

[0032] FIG. **2** illustrates a second exemplary embodiment of a power receiver.

[0033] FIG. **3** illustrates a third exemplary embodiment of a power receiver.

[0034] FIG. **4** illustrates a fourth exemplary embodiment of a power receiver.

[0036] FIG. **6**A is an exploded perspective view of an exemplary ground antenna array for the power receiver.

[0037] FIG. **6**B is a perspective view of an assembled ground antenna array before being deployed.

[0038] FIG. **6**C is a perspective view of an assembled ground antenna array after being deployed.

[0039] FIG. **7**A is a side view of an insertion tool for installing the ground antenna array.

[0040] FIG. **7**B is a top view of the insertion tool for installing the ground antenna array.

[0041] FIG. **7**C is a bottom view of the insertion tool for installing the ground antenna array.

DETAILED DESCRIPTION

[0042] Referring now to the drawings, a power receiver for extracting energy from the earth's electric field are illustrated and indicated generally by the numeral **10**. Various embodiments of the power receiver **10** are described and similar reference numbers are used throughout the description to indicate similar components.

[0043] The power receiver **10** converts energy in the ELF/ULF waves to useful form, e.g. 60 Hz AC or DC. The power receiver **10** is essentially a resonance circuit that resonates at the natural resonance frequencies in the earth's electric field. These resonance frequencies, known as Schumann resonance frequencies, occur at 7.83 Hz, 14.3 Hz, 20.8 Hz, 27.3 Hz, and 33.8 Hz. A high voltage impulse initiates resonance within the power receiver **10**. In the resonant mode, the impedance of the power receiver **10** is reduced to near zero thus inducing ground currents to flow into the power receiver **10** where the ground currents are converted to useful form.

[0044] FIG. **1** illustrates a first embodiment of the power receiver **10**. The power receiver **10** comprises a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. In this embodiment, the elevated terminal **15** is capacitively coupled to electric fields within the earth's ionosphere cavity and functions as an upper capacitive plate. A lower capacitive plate **20** is connected to the ground terminal **25** beneath the surface of the earth.

[0045] The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45**, and capacitor **50**. One end of the primary winding **35** is connected to the lower capacitive plate **20** and ground terminal **25**. The opposite end of the primary winding **35** is connected via a spark gap **90** to the elevated terminal **15**. The capacitor **50** is connected in parallel with the primary winding **35** of the resonant transformer **30** to form an LC circuit **55** with a resonance frequency range of between about 0.1 and 200 Hz. In a preferred embodiment, the resonant transformer has a Q of about 10 or greater and resonance frequency in the range of about 0.1-200 Hertz. For example, the resonant transformer 30 may have a resonance frequency of about 7.83 Hz, the fundamental Schumann resonance frequency. The secondary winding **40** of the resonant transformer **30** is connected to a power converter **110** as will be hereinafter described in greater detail. The power converter **110** converts the energy extracted from the earth's electric field by the power receiver **10** into a usable form for driving a load **140**.

[0046] The elevated terminal/upper capacitive plate **15** comprises an insulated, dish-shaped plate with a large radius of curvature. The capacitance and resistance of the elevated terminal is chosen for receiving broadband electric field frequencies in the 0-200 Hz range. The upper capacitive plate **15** is sized to maximize to the extent practical coupling with the electric field in the earth's ionosphere cavity.

[0047] The lower capacitive plate **20** is also a dish-shaped plate with a large radius of curvature. One function of the lower capacitive plate **20** is to collect charge from the earth's ground currents and provide an instantaneous source of current as hereinafter described. The capacitance and resistance of the lower capacitive plate **20** is selected to promote the flow of current from the ground with minimal losses.

[0048] The spark gap **90** connected between the elevated terminal **15** and resonant transformer **30** comprises a pair of electrodes **95**, **100** separated by an evacuated air gap **105**. Electrode **95** is connected to the upper capacitive plate **15**. Electrode **100** is connected to the resonant transformer **30**. The spark gap **105** prevents electrical discharge from the upper capacitive plate **15** to the earth's ionosphere cavity. The spark gap **90** in combination with the elevated terminal **15** function as an impulse generator that applies a high voltage impulse of about 10,000-40,000 volts to the primary winding **35** to initiate resonance in the transformer **30**.

[0049] In operation, the capacitive coupling of the upper capacitive plate **15** induces a high voltage operating current in the upper capacitive plate **15**. The upper capacitive plate is connected to a first electrode **95** to the spark gap **90**. When the voltage difference between the electrodes **95** and **100** reaches a threshold, a spark forms across the electrodes **95**,**100** and a high voltage impulse is applied to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance within the transformer **30**.

[0050] In resonant mode, the impedance of the resonance transformer is reduced to nearly zero allowing current to flow from the capacitive plate **20** and ground terminal **25** through the primary winding **35** of the transformer **30**, which in turn induces current in the secondary winding **40**. Power converter **110** converts the current flowing through the secondary winding **40** into a usable form for driving a load **140**. The transformer **30** will continue to resonate for a short period of time. By providing high voltage impulses to the primary winding **35** of the resonant transformer **30** at periodic intervals, it is possible to maintain a continuous flow of current from the earth into the resonant transformer **30**, thus producing a continuous supply of power.

[0051] FIG. **2** discloses a second embodiment of the primary receiver **10**. This embodiment includes a resonant transformer **30** connected between an elevated terminal **15** and ground terminal **25**. The resonant transformer **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and a high voltage capacitor **50**. One end of the primary winding **35** is connected to the ground terminal **25**. The opposite end of the primary winding **35** is connected to the elevated terminal **15**. The capacitor **50** has a capacitance of about 0.01 micro-farads. In contrast to the previous embodiment, capacitor **50** is connected in series with the primary winding **35** and elevated terminal **15** and forms a LC circuit **55** with a Q of about 10 or greater and a resonance frequency in the range of about 0.1 to 200 Hz. In a preferred embodiment, the resonance frequency of the transformer **30** is 7.83 Hz, the fundamental Schumann resonance frequency. An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse to the primary winding **35** of the resonant transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. As previously described, the high voltage impulse applied by the impulse generator **60** initiates resonance within the resonant transformer **30** inducing current flow from the ground terminal **25** into the primary winding **35** of the resonant transformer **30**. The flow of current from the ground terminal **25** through the primary winding **35** induces current in the secondary winding **40**. Power converter **110** converts the electrical energy in the current flowing through the primary winding **40** into a usable form.

[0052] In contrast to the first embodiment, it is not required to capacitively couple the elevated terminal **15** in the second embodiment to the earth's ionosphere cavity. Rather, the elevated terminal **15** in this embodiment provides lightning protection and dissipates some of the energy flowing into the power receiver **10** to the earth's ionosphere cavity. Also, in contrast to the first embodiment, the capacitor **50** is connected in series between the primary winding **35** of the transformer **30** and the elevated terminal **15**. Those skilled in the art will appreciate that the capacitor **50** could also be connected in parallel rather than series with the primary winding **35** as shown in FIG. **1**. Another difference is that the impulse generator **60** has an external power source. The amount of energy generated by the power receiver **10**, however, is far greater than the energy needed to generate high voltage impulses. The first embodiment does not require an external power source to generate high voltage impulses.

[0053] FIG. **3** illustrates a third embodiment of the power receiver **10**. This embodiment is essentially the same as the embodiment shown in FIG. **2**. The main difference is that a center tap of the primary winding **35** in the resonant transformer **30** is connected to an electrical ground **85**. It should be appreciated that the electrical ground **85** may be different than the earth ground. When the center tap of the resonant transformer **30** is grounded at a distance away from the ground terminal **25** (e.g. 50 ft to 100 ft), the power receiver **10** becomes a transmitter via the ground loop formed.

[0054] FIG. **4** illustrates the power receiver **10** of FIG. **2** in greater detail. The power receiver includes a resonant transformer **30** connected between a ground terminal **25** and an elevated terminal **15**. The ground terminal **25** may comprise a ⅝-inch×8-foot copper ground rod, such as the ERICO 615880UPC. The elevated terminal **15** may comprise a 90% copper mesh formed into a hemisphere with a radius of about 9 inches. The elevated terminal **15** may be elevated at a height of approximately 6 feet above the ground.

[0055] The resonant transformer **30** includes a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50** configured as previously described. The resonant transformer **30** may have a Q of about **10** and a resonance frequency in the range of about 0.1 to 200 Hz. The resonant transformer **30** may be made using an Allanson transformer (part #1530BP120R) connected in series with a 0.01 micro-farad capacitor, such as the Condensor Products high voltage capacitor (part 190 TC 103-17-125). The resonant transformer **30** is used in a step-down configuration. The center tap of the resonant transformer **30** may optionally be connected to a ground.

[0056] An impulse generator **60** is connected between the primary winding **35** of the resonant transformer **30** and the series capacitor **50** and applies a high voltage impulse in the range of about 10,000 to 40,000 volts to the primary winding of the transformer **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** connects to the secondary winding **40** of the resonant transformer **30** for converting current in the secondary winding of the transformer to a useful form.

[0057] The impulse generator **60** comprises a pulse generator **65** for generating low voltage pulses, a step-up transformer **80** for converting the low voltage pulses from the pulse generator **65** to high voltage pulses, and a spark gap **90** for generating sparks responsive to the high voltage pulses from the step-up transformer **80**.

[0058] The pulse generator **65** comprises a square wave generator **70**, such as a Sinometer VC2002 function signal generator, and solid state relay **75**. The square wave generator **70** generates a digital pulse stream. In one embodiment, the digital pulse stream generates a square waveform with a frequency of about 7.83 Hz. The frequency of the digital pulse stream is selected to match the resonance frequency of the transformer **30**, though such is not necessarily required. The pulse stream output from the square wave generator **70** is applied to the solid state relay **75**. The solid state relay **75** is connected between a battery or other power source and a first winding of the step-up transformer **80**. The battery may comprise a 12 V, 7.0 A/H sealed lead acid battery, such as the ELB 1270A by Lithonia Lighting. The solid state relay **75** functions as a switch that is activated responsive to the waveform from the square wave generator **70** to provide a continuous stream of low voltage pulses from the battery to the first winding of the step-up transformer **80**. A 1 ohm resistor is connected between the solid state relay **75** and step-up transformer **80**.

[0059] The step-up transformer **80** may comprise a Transco 15 kV, 30 mA neon sign transformer (part #S15612). The step-up transformer **80** converts the low voltage pulses from the pulse generator **65** to high voltage pulses that are applied to the spark gap **90**. The step-up transformer has a 0.5 micro-farad capacitor connected in parallel with the primary winding of the step-up transformer **80**. The step-up transformer produces pulses at the output of about 30,000 to 40,000 volts.

[0060] The spark gap **90** comprises a pair of electrodes **95**, **100** separated by an air gap **105**. A suitable spark gap electrode pair is the Information Unlimited SPARK05 ¼-inch×1-inch tungsten electrodes. As previously described, when the voltage potential between the electrodes **95**, **100** reaches a threshold, a spark forms between the electrodes **95**, **100** and supplies a nearly instantaneous, high voltage impulse to the primary winding **35** of the resonant transformer **30**. This high voltage impulse initiates resonance in the resonant transformer **30** inducing current flow from the ground terminal **25** through the primary winding **35** of the resonant transformer **30**.

[0061] The power converter **110** comprises a bridge rectifier **115**, filter capacitor **120**, charge controller **125**, and inverter **135**. A suitable rectifier is the Micro Commercial Components **10** amp, 1000 volt bridge rectifier (Part #GBJL 1010). The bridge rectifier **115** converts the AC current flowing through the secondary winding **40** of the resonant transformer to a DC current. A filter capacitor **120** removes unwanted frequencies from the DC current. A suitable capacitor **120** is Cornell Dubilier 1000uF 450VDC capacitor (part #383LX102M450N082). The filter capacitor **120** has a capacitance of about 1000 micro-farads. The DC current is input to the charge controller **125**. The charge controller **125** may, for example, comprise a maximum power point tracking (MPPT) charge controller, such as a Tracer **4215** BN MPPT Solar Charge Controller, which is commonly used in solar power generating systems. The charge controller **125** applies a small amount of energy to a battery **30** to charge the battery **130**. As previously noted, the battery **130** serves as a power source for the impulse generator **60**. The remaining current is supplied to an inverter **135**, which converts the DC current to an AC current with a desired voltage and frequency, e.g., 120 volts/60 Hz AC. A suitable inverter **135** is the 1500 W Pure Sine power inverter (AIMS)(part #PWR11500125).The power converter **110** as shown in FIG. **4** may be utilized in the embodiment shown in FIGS. **1**, **2** and **3**.

[0062] FIG. **5** illustrates a power receiver **10** according to another embodiment. The power receiver **10** comprises a plurality of resonant transformers **30** connected between a ground terminal **25** and elevated terminal **15**. Each of the resonant transformers **30** comprises a primary winding **35**, secondary winding **40**, ferromagnetic core **45** and series capacitor **50**. The primary windings **35** of the resonant transformers **30** are connected in parallel. The secondary windings **40** are connected in series with the power converter **110**. An impulse generator **60** applies a high voltage impulse to the primary windings **35** of the resonant transformers **30**. A battery **130** or other external power source supplies power to the impulse generator **60**. The power converter **110** converts the current in the power converter circuit to a usable form for driving a load **140**.

[0063] In one embodiment, each of the resonant transformers **30** shown in FIG. **5** is configured to have a different resonant frequency. In one embodiment, the resonant transformers **30** are configured to resonate at frequencies of 7.83 Hz, 14.8 Hz, 20.3 Hz and 26.8 Hz respectively. Additional resonant transformers **30** could be added to operate at other resonance frequencies.

[0064] FIGS. **6A-6C** illustrate a high quality ground antenna array **200** which may be used as a ground terminal **25**. The ground antenna array **200** comprises a generally cylindrical ground shaft **205** disposed with a hollow cylinder **220** and a plurality of reinforced, heavy gauge ground wires **210** attached at one end to the ground shaft **205**. The ground shaft **205** and ground wires **210** should be highly conductive and have low resistance to supply current from the ground to the power receiver **10**. In one embodiment, the ground wires **210** may be copper or other highly-conductive metal. The end of the ground shaft may be pointed to facilitate insertion into the earth. A connection port on the ground shaft **220** is provided to electrically connect the ground antenna array **220** to the resonant transformer **30**.

[0065] The hollow cylinder **220** has external threads **25** to facilitate insertion into the ground. A rotator nut **235** is fixedly secured to the top end of the hollow shaft **220**. A square shaft **215** protrudes from the top end of the ground shaft **205** into the opening in the rotator nut **235**. FIG. **6B**. A tool **250**, shown in FIG. **7**, engages with the rotator nut **235** and square shaft **215** during insertion of the ground antennas array **200** into the ground as will be hereinafter described.

[0066] The insertion tool **250** is shown in FIG. **7**. The insertion tool **250** includes a tool body **255** having a first socket **260** on one side to fit the rotator nut **235** on the hollow cylinder **220** and a second socket **265** on the other side to fit the square shaft **215** on the ground shaft **205**. Arms **270**

extend from the outer periphery of the tool body **255** for manually or mechanically turning the insertion tool **250**.

[0067] Before the antenna array **200** is deployed, the ground wires **210** are wound around the ground shaft **205** with the free ends protruding slightly from respective openings **230** in the hollow cylinder **220** to a distance not to exceed one half (½) the depth of the external threads **225** on the hollow cylinder **220**. FIG. **6**B illustrates the ground antenna array **200** before deployment. FIG. **6**C illustrates the ground antenna array in a deployed configuration.

[0068] Installation of the ground antenna array **200** is performed in two stages. In the first stage, a hole slightly smaller in diameter than the threads **235** of the hollow cylinder **220** is drilled into the Earth to a depth matching the length of the hollow cylinder **220** or slightly longer. The hole is filled with water and the water is allowed to soak into the soil. After the ground is softened, the hollow cylinder **220** is rotated using the insertion tool **250** to insert the ground antenna array **200** into the ground. The first socket **260** of the insertion tool **250** is engaged with the rotator nut **230** and the insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to thread the ground assembly into the hole. During the initial insertion of the ground antenna array **200**, the ground shaft **205** is fixed to the hollow shaft **220** and rotates with the hollow shaft. The hollow cylinder **220** is rotated until it reaches the full depth of the hole.

[0069] Once the ground antenna array **200** has been fully inserted into the earth, the insertion tool **250** is flipped over and the second socket **265** of the insertion tool **250** is engaged with the square shaft **215**. The insertion tool **250** is turned by hand or a mechanized rotating shaft fitted and attached to the tool arms **270** to rotate the ground shaft **205**. During the second phase, the ground shaft **205** rotates freely inside the hollow cylinder **220**. Rotation of the ground shaft **205** causes the reinforced ground wires **210** to extend radially into the earth. The ground shaft **220** is rotated until the ground wires are fully extended. The ends of the ground wires may be sharpened to aid in the extension of the ground wires during the second phase.

[0070] After the ground antenna array **200** is deployed, a connection cable **280** is attached to a connection port **240** on the ground shaft **220** to electrically connect the ground antenna array **220** to the resonant transformer **30** in the power receiver **10**.

1. A power receiver for extracting electrical energy from the earth's electric field, said power receiver comprising:
- a resonant transformer connected to a ground terminal disposed below the surface of the earth;
- an impulse generator for generating and applying a high voltage electrical impulse to a primary winding of the resonant transformer to induce an alternating current flow from the ground terminal through the transformer; and
- a power converter connected to a secondary winding of the resonant transformer to convert an alternating current flowing through the secondary winding to a direct current.

2. The power receiver of claim **1** wherein a resonant frequency of the resonant transformer is below 200 Hz.

3. The power receiver of claim **1** wherein the resonant transformer comprises a ferro- resonant transformer.

4. The power receiver of claim **1** wherein the impulse generator comprises:
- a pulse generator for generating low voltage pulses;
- a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;
- a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

5. The power receiver of claim **1** wherein the impulse generator comprises a solid state spark generator.

6. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

7. The power receiver of claim **1** wherein said resonant transformer includes a capacitor connected in series with the primary winding.

8. A method of extracting electrical energy from the earth's electric field, the method comprising:
- applying a high voltage electrical impulse to a primary winding of a resonant transformer connected to a ground terminal disposed below the surface of the earth to induce an alternating current flow from the ground terminal through the transformer; and
- converting an alternating current flowing through a secondary winding of the resonant transformer to a direct current.

9. The method of claim **8** wherein a resonant frequency of the resonant transformers is below 200 Hz.

10. The method of claim **8** wherein the resonant transformer comprises a ferro-resonant transformer.

11. The method of claim **8** wherein the impulse generator comprises:
- a pulse generator for generating low voltage pulses;
- a step-up transformer for converting the low voltage pulses provided by the pulse generator to high voltage impulses;
- a spark gap connected between the step-up transformer and the primary winding of the resonant transformer to generate a spark responsive to the high voltage impulses from the step-up transformer.

12. The method of claim **8** wherein the impulse generator comprises a solid state spark generator.

13. The method of claim **8** wherein said resonant transformer includes a capacitor connected in parallel with the primary winding.

14. The method of claim **8** wherein said resonant transformer includes a capacitor connected in series with the primary winding.

To use earbuds/iPhone earpods with a crystal radio you need to insert a transformer where the crystal earpieces would normally connect to a crystal radio. The jack for the earbuds would be connected to the transformer. Technically speaking, this is for purposes of impedance matching. Below is a diagram for one such crystal radio and some sample photos.

Crystal radio with crystal earpiece.

In the photo below are shown the transformers I've tried. Note that the transformer needs to be a *step-up* or *step-down* transformer. I'm not certain that a one-to-one transformer will work. The three smaller ones all gave around the same results. The large microwave oven transformer didn't work as well; the sound was too quiet.

Transformers I've tried with earbuds.

transformer

How to determine which side of the transformer to use where

A transformer has two coils/sides and each coil has two wires coming from it. You need to connect the two wires from one side to the crystal radio and the two wires from the other side to the earbuds.

Here are some ways to determine which side goes where. See the corresponding diagrams and photos below. The side that connects to the crystal radio is the side:

- that's labelled with the higher voltage,
- that has the coil with the most turns, or
- that has the highest resistance.

Determining using labelled input/output voltages.

MAHARSHI BHARADWAAJA'S

VYMAANIKA-SHAASTRA

OR

SCIENCE OF AERONAUTICS

Part of his unknown work

"YANTRA SARVASVA"

or

"ALL ABOUT MACHINES"

as revealed to venerable

Pandit SUBBARAYA SASTRY

and recorded in hand-written

Sanskrit Manuscript Form

translated into English by

G. R. JOSYER, M.A., Hons., F.R.E.S., M.R.S.L.

Founder Director,

INTERNATIONAL ACADEMY OF SANSKRIT RESEARCH.

Printed at the

CORONATION PRESS, MYSORE 4. INDIA.

Title page of the English translation of Vyamanika Shastra published in 1973

Vaimanika Shastra

The Vaimānika Shāstra वैमानिक शास्त्र ("Science of Aeronautics" [1]; also *Vimanika, Vymanika*) is an early 20th century Sanskrit text on aeronautics, claimed to be obtained by mental channeling, about construction of *vimāna*s, the "chariots of the Gods", self-moving aerial cars mentioned in the Sanskrit epics.

The existence of the text was revealed in 1952 by G. R. Josyer, according to whom it is due to one Pandit Subbaraya Shastry, who dictated it in 1918-1923. A Hindi translation was published in 1959, the Sanskrit text with an English translation in 1973. It has 3000 shlokas in 8 chapters and was attributed by Shastry to Maharishi Bharadvaja, [2] which makes it of purportedly "ancient" origin, and hence it has a certain notability in ancient astronaut theories.

A study by aeronautical and mechanical engineering at Indian Institute of Science, Bangalore in 1974 concluded that the aircraft described in the text were "poor concoctions" and that the author showed a complete lack of understanding of aeronautics. [3]

Origin and publication

Subbaraya Shastry was a mystic from Anekal, who was reputed to speak out verses (*slokas*) whenever he got inspiration, described by Josyer as "a walking lexicon gifted with occult perception". According to Josyer, he dictated the text to G. Venkatachala Sharma in the early 1900s (completing it in 1923).

Subbaraya Shastry died in 1941, and Venkatachala took his manuscripts into keeping. The Vaimanika Shastra manuscript appeared at Rajakiya Sanskrit Library, Baroda by 1944.[4] The text was published in Hindi in 1959 [5] and later in English by G.R. Josyer, titled *Vymanika Shastra*. Josyer's edition, also added illustrations drawn by T. K. Ellappa, a draughtsman at a local engineering college in Bangalore, under the direction of Shastry, which had been missed in the 1959 edition. [6]

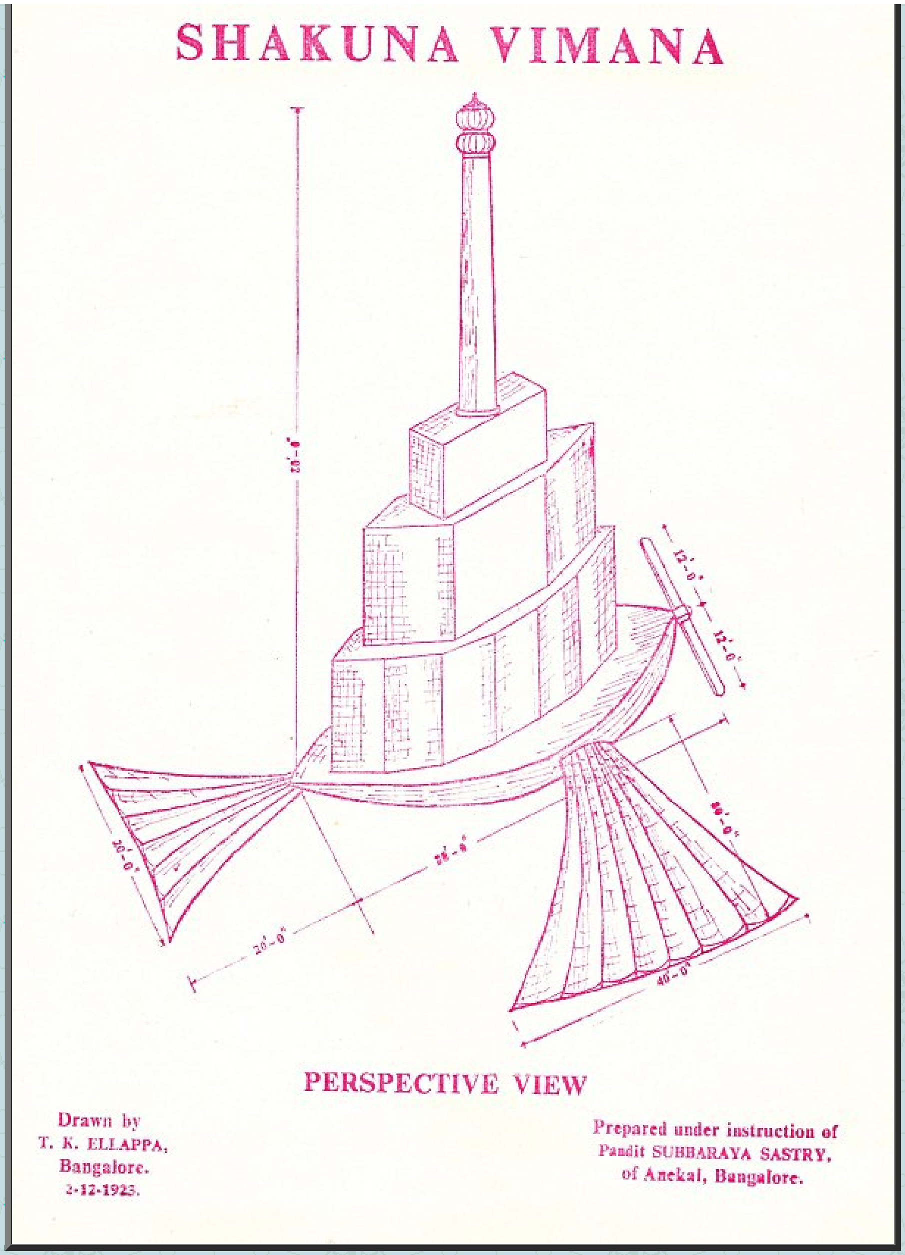
Its existence was first announced publicly in a 1952 press release by G.R. Josyer, who had founded his "International Academy of Sanskrit Research" in Mysore the year before. In the foreword to the 1973 publication that contained the full Sanskrit text with English translation, Josyer quotes a 1952 press release of his which was "published in all the leading dailies of India, and was taken up by Reuter and other World Press News Services":[7]

> **Mr. G. R. Josyer, Director of the International Academy of Sanskrit Research in Mysore, in the course of an interview recently, showed some very ancient manuscripts which the Academy had collected. He claimed that the manuscripts were several thousands of years old, compiled by ancient rishis, Bharadwaja, Narada and others, dealing, not with the mysticism of ancient Hindu philosophy of Atman or Brahman, but with more mundane things vital for the existence of man and progress of nations both in times of peace and war. [...] One manuscript dealt with Aeronautics, construction of various types of aircraft for civil aviation and for warfare. [...] Mr. Josyer showed some types of designs and drawing of a helicopter-type cargo-loading plane, specially meant for carrying combustibles and ammunition, passenger aircraft carrying 400 to 500 persons, double and treble-decked aircraft. Each of these types had been fully described.**

Josyer then tells how he was visited by "Miss Jean Lyon, journalist of Toronto and New York" for an interview, and how Lyon in her *Just Half a World Away* (1954) concluded that he was "guilty of a rabid nationalism, seeking to wipe out everything since the Vedas".

A critical review pronounced Josyer's introduction to be "least scholarly by any standards." and said that "the people connected with publication – directly or indirectly – are solely to blame either for distorting or hiding the history of the manuscripts." perhaps in an attempt to "eulogise and glorify whatever they can find about our past, even without valid evidence". By tracing the provenance of the manuscript, interviewing associates of S. Shastry (including G. V. Sharma to whom the text was originally dictated), and based on the linguistic analysis of the text, the review concluded that it came into existence sometime between 1900 and 1922.[6]

Structure and content



An illustration of the Shakuna Vimana that is supposed to fly like a bird with hinged wings and tail.[6]

Unlike modern treatises on aeronautics that begin by discussing the general principles of flight before detailing concepts of aircraft design, the *Vaimanika Shastra* straightaway gets into quantitative description, as though a particular aircraft is being described. The topics covered include, "definition of an airplane, a pilot, aerial routes, food, clothing, metals, metal production, mirrors and their uses in wars, varieties of machinery and yantras, planes like 'mantrik', 'tantrik', and 'kritak'" and four planes called *Shakuna*, *Sundara*, *Rukma*, and *Tripura* are described in greater detail. The extant text is claimed to be only a small (one-fortieth) part of a larger work *Yantra Sarvaswa* ("All about machines[7]) composed by Maharishi Bharadwaj and other sages for the "benefit of all mankind".[6]

In 1991, the English portion and the illustrations from the Josyer book were reprinted by David Hatcher Childress in *Vimana Aircraft of Ancient India & Atlantis* as part of the *Lost Science Series*. According to Childress, the 8 chapters treat the following:

- **The secrets of constructing aeroplanes, which will not break, which cannot be cut, will not catch fire, and cannot be destroyed.**
- **The secret of making planes motionless.**
- **The secret of making planes invisible.**
- **The secret of hearing conversations and other sounds in enemy places.**
- **The secret of retrieving photographs of the interior of enemy planes**
- **The secret of ascertaining the direction of enemy planes approach.**
- **The secret of making persons in enemy planes lose consciousness.**
- **The secret of destroying enemy planes.**

The propulsion of the Vimanas according to Kanjilal (1985) is by a "Mercury Vortex Engines"[8], apparently a concept similar to electric propulsion. Childress finds evidence for this "mercury vortex engine" in the *Samarangana Sutradhara*, an 11th century treatise on architecture.

J. B. Hare of the Internet Sacred Text Archive in 2005 compiled an online edition of Josyer's 1973 book, in the site's "UFOs" section. In his introduction, Hare writes

> **The *Vymanika Shastra* was first committed to writing between 1918 and 1923, and nobody is claiming that it came from some mysterious antique manuscript. The fact is, there are no manuscripts of this text prior to 1918, and *nobody is claiming that there are*. So on one level, this is not a hoax. You just have to buy into the assumption that 'channeling' works. ... there is no exposition of the theory of aviation (let alone antigravity). In plain terms, the VS never directly explains how Vimanas get up in the air. The text is top-heavy with long lists of often bizarre ingredients used to construct various subsystems. ... There is nothing here which Jules Verne couldn't have dreamed up, no mention of exotic elements or advanced construction techniques. The 1923 technical illustration based on the text ... are absurdly un-aerodynamic. They look like brutalist wedding cakes, with minarets, huge ornithopter wings and dinky propellers. In other words, they look like typical early 20th century fantasy flying machines with an Indian twist.**

A 1974 study by researchers at the Indian Institute of Science, Bangalore found that the heavier-than-air aircraft that the *Vaimanika Shastra* described were aeronautically unfeasible. The authors remarked that the discussion of the principles of flight in the text were largely perfunctory and incorrect, in some cases violating Newton's laws of motion. The study concluded:[9]

> **Any reader by now would have concluded the obvious – that the planes described above are the best poor concoctions, rather than expressions of something real. None of the planes has properties or capabilities of being flown; the geometries are unimaginably horrendous from the point of view of flying; and the principles of propulsion make then resist rather than assist flying. The text and the drawings do not correlate with each other even thematically. The drawings definitely point to a knowledge of modern machinery. This can be explained on the basis of the fact that Shri Ellappa who made the drawings was in a local engineering college and was thus familiar with names and details of some machinery. Of course the text retains a structure in language and content from which its 'recent nature' cannot be asserted. We must hasten to point out that this does not imply an oriental nature of the text at all. All that may be said is that thematically the drawings ought to be ruled out of discussion. And the text, as it stands, is incomplete and ambiguous by itself and incorrect at many places.**

The authors expressed puzzlement at the contradiction and errors in the *Vaimanika Shastra* text, especially since its compilers supposedly had access to publications that did not make such errors (such as, Dayanand Saraswati's commentary on the Rigveda published in 1878 or earlier).[10]

Ancient Indian Vimanas and Modern Mercury Vortex Technology

Vimanas

This article deals with vimanas that are running on a mercury vortex propulsion system. This system is developed by, created by Bill Clendenon, an inventor of the mercury vortex propulsion system. Clendenon explains that the vimana was an ancient Indian aircraft, mention in variuous Vedic scriptures. This was a machine driven by a now unconventional manner. The mercury vortex propulsion engine.

The workings of the mercury vortex technology

David hatcher Childress has explained a bit further, the theory of the mercury vortex technology. I will quote it here in full:

- The electromagnetic field coil, which consists of the closed circuit exchanger / condenser coil circuit containing the liquid metal mercury and / or its hot vapor, is placed with its core axis vertical to the craft.
- A ring conductor (directional gyro-armature) is placed around the field coil (heat exchanger) windings so that the core of the vertical heat exchanger coils protrudes through the center of the ring conductor.
- When the electromagnet (heat exchanger coils) is energized, the ring conductor is instantly shot into the air, taking the craft as a complete unit along with it.
- If the current is controlled by a computerized resistance, (rheostat), the ring conductor armature and craft can be made to hover or float in the Earth's atmosphere.
- The electromagnet hums and the armature ring (or torus) becomes quite hot. In fact, if the electrical current is high enough, the ring will glow dull red or rust orange with heat.
- The phenomenon (outward sign of a working law of nature) is brought about by an induced current effect identical with an ordinary transformer.
- As the repulsion between the electromagnet and the ring conductor is mutual, one can imagine the craft being affected and responding to the repulsion phenomenon as a complete unit.
- Lift or repulsion is generated because of close proximity of the field magnet to the ring conductor. Clendenon says that lift would always be opposed to the gravitational pull of the planet Earth, but repulsion can also be employed to cause fore and aft propulsion.'(David hatcher Childress (2000), p.180)

The basic turbo-pump engine has four main sections: compressor, combustion, or heating chambers, turbo-pump and exhaust. Burning gases are exhausted through the turbo-pump wheel to generate power to turn the electric generator:

1. Propellant tanks will be filled with liquid air (obtained directly from the atmosphere by on-board reduction equipment).
2. Liquid air may be injected into expansion chambers and heated by the metal working-fluid mercury confined in a boiler coupled to a heat exchanger.
3. The super heated M.H.D. plasma (or air) will expand through propellant cooled nozzles.
4. The ship may recharge its propellant tanks with liquid air and condensate water collected directly from the upper atmosphere by the on-board reducing plant.

Important is that this mercury vortex propulsion model is intented for terrestrial flight only. The strange ball of light that is often seen by UFO like craft, is the ball of light that surrounds a craft is: the magneto-hydrodynamic plasma, a hot continuously recirculating air flow through the ship's gas turbine which is ionized (electrically conducting). Magnetohydrodynamics (MHD) is described by Childress as an ionized gas that is passed through a magnetic field to generate electricity. (Childress (2000), p.182)

This effect of the ball of light makes the craft to appear alive and breathing. The reason why ships disappear from view is according to Clendenon: The ionized bubble of air surrounding the UFO may be controlled by a computerized rheostat so the ionization of the air may shift through every color of the spectrum, obscuring the aircraft from view. (Childress (2000), p. 181)

Here is a scientific view on the socalled invisiblility of aerial craft. All these ideas are taken from an ancient manuscript the Vimaana Shaastra. In this manuscript there are many detailed characteristists about what could very possible have been mercury vortex generators. These mercury vortex generators could have been used in various types of vimanas.

Dangers of mercury vortex propulsion

Clendenon points out the danger of this mercury vortex propulsion system. When the liquid metal mercury is heated, it gives forth a hot vapor. This hot vapour is deadly poisonous, because; '... if the liquid metal mercury is made radioactive and heated sufficiently to emit radiation, any leaks in the mercury would, therefore, be a double danger to the crew and maintenance personnel of any vehicle powered by a mercury vapor turbine.'(Quoted from the book by Bill Clendenon and David Hatcher Childress, Mercury: UFO Messengers of the Gods, 1990, p. 85)

UFOs and Vimanas
By Stephen Knapp

In supplying information about the advancements of Vedic science, the subject of Vedic airplanes, vimanas, is almost in a classification of its own. Some of this information is so amazing that for some people it may border science fiction. Nonetheless, as we uncover and explain it, it provides serious food for thought.

First of all we need to understand that the Vedic conception of universal time is divided into different periods. For example, a period called one day of Brahma is equivalent to 4,320,000,000 of our years on earth. Brahma's night is equally as long and there are 360 of such days and nights in one year of Brahma. Each day of Brahma is divided into one thousand cycles of four yugas, namely Satya-yuga, Treta-yuga, Dvapara-yuga, and finally the Kali-yuga, which is the yuga we are presently experiencing. Satya-yuga lasts 1,728,000 years, and is an age of purity when all residents live very long lives and can be fully developed in spiritual understanding and mystical abilities and remarkable powers. Some of these abilities, or mystic siddhis, include changing one's shape, becoming very large or microscopically small, becoming very heavy or even weightless, securing any desirable thing, becoming free of all desires, or even flying through the sky to wherever one wanted to go on one's own volition. So at that time, the need for mechanical flying machines was not necessary.

As the yugas continued, the purity of the people, along with their mystical abilities, decreased by 25% in each age. The age of Treta-yuga lasts 1,296,000 years. During that age, the minds of humanity became more dense, and the ability for understanding the higher spiritual principles of the Vedic path was also more difficult. Naturally, the ability to fly through the sky by one's own power was lost. After Treta-yuga, Dvapara-yuga lasts 864,000 years, and Kali-yuga lasts 432,000 years, of which 5,000 have now already passed. At the end of Kali-yuga, the age of Satya-yuga starts again and the yugas continue through another cycle. One thousand such cycles is one day of Brahma. Now that we are in Kali-yuga, almost all spiritual understanding disappears, and whatever mystical abilities that remain are almost insignificant.

It is explained that it was not until the beginning of Treta-yuga that the development of vimanas took place. In fact, Lord Brahma, the chief demigod and engineer of the universe, is said to have developed several vimanas for some of the other demigods. These were in various natural shapes that incorporated the use of wings, such as peacocks, eagles, swans, etc. Other vimanas were developed for the wiser human beings by great seers of Vedic knowledge.

In the course of time, there were three basic types of vimanas. In Treta-yuga, men were adept in mantras or potent hymns. Thus, the vimanas of that age were powered by means of knowledge of mantras. In Dvapara-yuga, men had developed considerable knowledge of tantra, or ritual. Thus, the vimanas of Dvapara-yuga were powered by the use of tantric knowledge. In Kali-yuga, knowledge of both mantra and tantra are deficient. Thus, the vimanas of this age are known as kritaka, artificial or mechanical. In this way, there are three main types of vimanas, Vedic airplanes, according to the characteristics of each yuga.

Of these three types, there is listed 25 variations of the mantrika vimanas, 56 variations of the tantrica vimanas, and 25 varieties of the kritakaah vimanas as we find today in Kali-yuga. However, in regard to the shape and construction, there is no difference between any of these vimanas, but only in how they were powered or propelled, which would be by mantras, tantras, or mechanical engines.

The controversial text known as Vimaanika Shastra, said to be by Maharshi Bharadwaja, also describes in detail the construction of what is called the mercury vortex engine. This is no doubt of the same nature as the Vedic Ion engine that is propelled by the use of mercury. Such an engine was built by Shivkar Bapuji Talpade, based on descriptions in the Rig-veda, which he demonstrated in Mumbai (Bombay), India in 1895. I more fully explained this in Chapter Three of this volume. Additional information on the mercury engines used in the vimanas can be found in the ancient Vedic text called the Samarangana Sutradhara. This text also devotes 230 verses to the use of these machines in peace and war. We will not provide the whole description of the mercury vortex engine here, but we will include a short part of William Clendenon's translation of the Samarangana Sutradhara from his 1990 book, Mercury, UFO Messenger of the Gods:

"Inside the circular air frame, place the mercury-engine with its electric/ultrasonic mercury boiler at the bottom center. By means of the power latent in the mercury which sets the driving whirlwind in motion, a man sitting inside may travel a great distance in the sky in a most marvelous manner. Four strong mercury containers must be built into the interior structure. When those have been heated by controlled fire from iron containers, the vimana develops thunder-power through the mercury. At once it becomes like a pearl in the sky."

This provides a most simplistic idea of the potential of the mercury engines. This is one kind of a propulsion mechanism that the vimanas of Kali-yuga may use. Other variations are also described. Not only do these texts contain directions on how to make such engines, but they also have been found to contain flight manuals, aerial routes, procedures for normal and forced landings, instructions regarding the condition of the pilots, clothes to wear while flying, the food to bring and eat, spare parts to have, metals of which the craft needs to be made, power supplies, and so on. Other texts also provide instructions on avoiding enemy craft, how to see and hear what occupants are saying in enemy craft, how to become invisible, and even what tactics to use in case of collisions with birds. Some of these vimanas not only fly in the sky, but can also maneuver on land and fly into the sea and travel under water.

There are many ancient Vedic texts that describe or contain references to these vimanas, including the Ramayana, Mahabharata, Rig-veda, Yajur-veda, Atharva-veda, the Yuktilkalpataru of Bhoja (12th century A.D.), the Mayamatam (attributed to the architect Maya), plus other classic Vedic texts like the Satapathya Brahmana, Markandeya Purana, Vishnu Purana, Bhagavata Purana, the Harivamsa, the Uttararamcarita, the Harsacarita, the Tamil text Jivakacintamani, and others. From the various descriptions in these writings, we find vimanas in many different shapes, including that of long cigars, blimp-like, saucer-shapes, triangular, and even double-decked with portholes and a dome on top of a circular craft. Some are silent, some belch fire and make noise, some have a humming noise, and some disappear completely.

These various descriptions are not unlike the reports of UFOs that are seen today. In fact, David Childress, in his book Vimana Aircraft of Ancient India & Atlantis, provides many reports, both recent and from the last few hundred years, that describe eye witness accounts of encounters with UFOs that are no different in size and shape than those described in these ancient Vedic texts. Plus, when the pilots are seen close up, either fixing their craft or stepping outside to look around, they are human-like, sometimes with a Oriental appearance, in clothes that are relatively modern in style. In other reports, we have read where the craft may have alien type beings on board along with ordinary humans navigating the craft.

Does this mean that these are ancient vimanas that still exist today? Are they stored in some underground caverns somewhere? Or are they simply modern-built, using the ancient designs as described in the Vedic texts? The UFOs that have been seen around the world may not be from some distant galaxy, but may be from a secret human society, or even military installation. However, many of the Vedic texts do describe interplanetary travel. So even if these space machines are from some other planet, they may be using the same principles of propulsion that have already been described in the universal Vedic literature. The answer awaits us.

Vedic Vimanas - 8 Years Before the Wright Brothers
Shivkar Bapuji Talpade

Orville Wright demonstrated on December 17th 1903 that it was possible for a ‘manned heavier than air machine to fly’. But, in 1895, eight years earlier, the Sanskrit scholar Shivkar Bapuji Talpade had designed a basic aircraft called Marutsakthi (meaning Power of Air) based on Vedic technology and had it take off unmanned before a large audience in the Chowpathy beach of Bombay. The importance of the Wright brothers lies in the fact, that it was a manned flight for a distance of 120 feet and Orville Wright became the first man to fly. But Talpade’s unmanned aircraft flew to a height of 1500 feet before crashing down and the historian Evan Koshtka, has described Talpade as the ‘first creator of an aircraft’.

As the world observes the one hundredth anniversary of the first manned flight, it is interesting to consider the saga of India’s 19th century first aircraft inventor for his design was entirely based on the rich treasury of India’s Vedas. Shivkar Bapuji

Talpade was born in 1864 in the locality of Chirabazar at Dukkarwadi in Bombay.

He was a scholar of Sanskrit and from his young age was attracted by the Vaimanika Sastra (Aeronautical Science) expounded by the great Indian sage Maharishi Bhardwaja. One western scholar of Indology Stephen-Knapp has put in simple words or rather has tried to explain what Talpade did and succeeded!

According to Knapp, the Vaimanika Shastra describes in detail, the construction of what is called, the mercury vortex engine the forerunner of the ion engines being made today by NASA. Knapp adds that additional information on the mercury engines can be found in the ancient Vedic text called Samaranga Sutradhara. This text also devotes 230 verses, to the use of these machines in peace and war. The Indologist William Clarendon, who has written down a detailed description of the mercury vortex engine in his translation of Samaranga Sutradhara quotes thus 'Inside the circular air frame, place the mercury-engine with its solar mercury boiler at the aircraft center. By means of the power latent in the heated mercury which sets the driving whirlwind in motion a man sitting inside may travel a great distance in a most marvellous manner. Four strong mercury containers must be built into the interior structure. When these have been heated by fire through solar or other sources the vimana (aircraft) develops thunder-power through the mercury.

NASA (National Aeronau-tical and Space Administra-tion) world's richest/ most powerful scientific organisation is trying to create an ion engine that is a device that uses a stream of high velocity electrified particles instead of a blast of hot gases like in present day modern jet engines. Surprisingly according to the bi-monthly Ancient Skies published in USA, the aircraft engines being developed for future use by NASA by some strange coincidence also uses mercury bombardment units powered by Solar cells! Interestingly, the impulse is generated in seven stages. The mercury propellant is first vapourised fed into the thruster discharge chamber ionised converted into plasma by a combination with electrons broke down electrically and then accelerated through small openings in a screen to pass out of the engine at velocities between 1200 to 3000 kilometres per minute! But so far NASA has been able to produce an experimental basis only a one pound of thrust by its scientists a power derivation virtually useless. But 108 years ago Talpade was able to use his knowledge of Vaimanika Shastra to produce sufficient thrust to lift his aircraft 1500 feet into the air!

According to Indian scholar Acharya, 'Vaimanika Shastra deals about aeronautics including the design of aircraft the way they can be used for transportation and other applications in detail. The knowledge of aeronautics is described in Sanskrit in 100 sections, eight chapters, 500 principles and 3000 slokas including 32 techniques to fly an aircraft. In fact, depending on the classifications of eras or Yugas in modern Kaliyuga aircraft used are called Krithakavimana flown by the power of engines by absorbing solar energies!' It is feared that only portions of Bharadwaja's masterpiece Vaimanika Shas-tra survive today.

The question that comes to one's mind is, what happened to this wonderful encyclopaedia of aeronautical knowledge accumulated by the Indian savants of yore, and why was it not used? But in those days, such knowledge was the preserve of sages, who would not allow it to be misused, just like the knowledge of atomic bombs is being used by terrorists today!

According to scholar Ratnakar Mahajan who wrote a brochure on Talpade. 'Being a Sanskrit scholar interested in aeronautics, Talpade studied and consulted a number of Vedic treatises like Brihad Vaimanika Shastra of Maharishi Bharadwaja Vimanachandrika of Acharya Narayan Muni Viman yantra of Maharish Shownik Yantra Kalp by Maharishi Garg Muni Viman Bindu of Acharya Vachaspati and Vimana Gyanarka Prakashika of Maharishi Dhundiraj'. This gave him confidence that he can build an aircraft with mercury engines. One essential factor in the creation of these Vedic aircraft was the timing of the Suns Rays or Solar energy (as being now utilised by NASA) when they were most effective to activate the mercury ions of the engine. Happily for Talpade Maharaja Sayaji Rao Gaekwad of Baroda a great supporter of the Sciences in India, was willing to help him and Talpade went ahead with his aircraft construction with mercury engines. One day in 1895 (unfortunately the actual date is not mentioned in the Kesari newspaper of Pune which covered the event) before an curious scholarly audience headed by the famous Indian judge/ nationalist/ Mahadeva Govin-da Ranade and H H Sayaji Rao Gaekwad Talpade had the good fortune to see his un manned aircraft named as 'Marutsakthi' take off, fly to a height of 1500 feet and then fall down to earth.

But this success of an Indian scientist was not liked by the Imperial rulers. Warned by the British Government the Maharaja of Baroda stopped helping Talpade. It is said that the remains of the Marutsakthi were sold to 'foreign parties' by the relatives of Talpade in order to salvage whatever they can out of their loans to him. Talpade's wife died at this critical juncture and he was not in a mental frame to continue with his researches. But his efforts to make known the greatness of Vedic Shastras was recognised by Indian scholars, who gave him the title of Vidya Prakash Pra-deep.

Talpade passed away in 1916 un-honoured, in his own country.

As the world rightly honours the Wright Brothers for their achievements, we should think of Talpade, who utilised the ancient knowledge of Sanskrit texts, to fly an aircraft, eight years before his foreign counterparts.

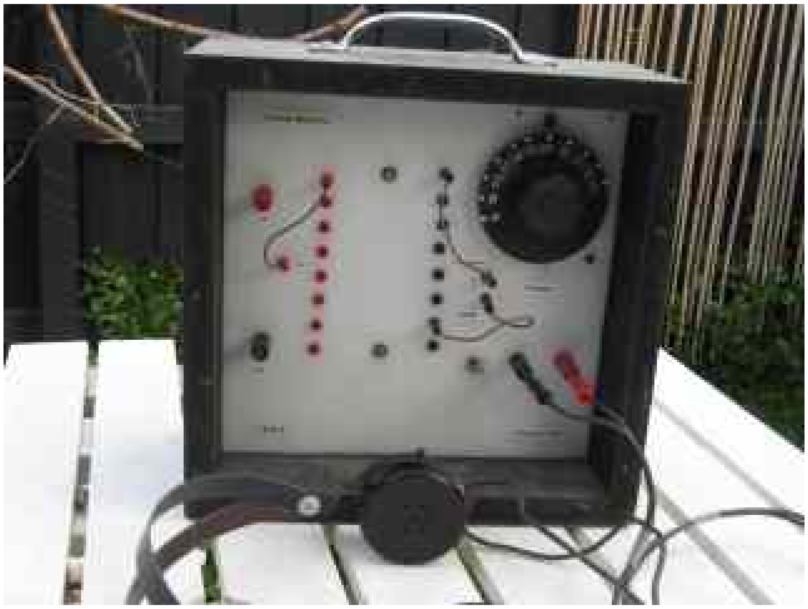
A simple crystal set for free power radio

Of any electronic project, the crystal set would have to rate as one of the most popular. Many amateurs are on the air today because of their early construction of a crystal set. Most practical electronic books for beginners include at least one crystal set project. Unfortunately, some of these circuits take simplicity too far and deliver mediocre performance, often by omitting key components such as the tuning capacitor, or failing to provide coil taps.



This article describes a crystal set of medium complexity. It features coil taps for the antenna and diode to make it useful for both country and metropolitan listeners. The taps allow the set to cover 160 metres if desired. All parts are easily obtainable, making it a good choice for the beginner. The endless possibilities for experimentation also make crystal sets interesting novelty projects for experienced constructors. The schematic is shown here:

Obtaining the parts

Tuning capacitor

A large air-spaced type, covering about 10 to 415 picofarads is preferred. These capacitors were common in valve and early transistor radios and often appear at hamfests. Their long shafts make it easy to attach large tuning knobs. When purchasing one see that the shaft turns freely, but is not loose. Ensure that the plates are straight and do not touch when meshed - use a multimeter (preferably with audible continuity function) to test this. Avoid capacitors with 3/8 inch shafts unless nothing else is available â€“ knobs for these are not obtainable, and an old valve radio dial drum will need to be used instead.

If a large capacitor is unavailable, a small plastic dielectric unit is suitable (such as stocked by Jaycar and online). The lower maximum capacitance (160 pF) means that more coil turns are required to provide coverage of the lower end of the broadcast band. This can be partially overcome by connecting the 60 and 160 pF sections in parallel (link the 'A' and 'O' tabs). The main disadvantage of these capacitors is their short shafts, which makes it harder to attach most types of knobs.

Vernier Drive and dial

The use of a vernier reduction drive is not necessary. However, its inclusion makes tuning easier, particularly on the higher frequencies. These are rare new but sometimes come up at hamfests. If your drive lacks a dial, one can be fashioned from a plastic or metal disc, such as a jar lid or salvaged computer hard disc. Glue the dial directly to the skirt of the tuning knob if you lack a vernier drive.

Diode

This is the most easily obtainable and cheapest component in the project. A germanium diode, such as a 1N60, 0A90, 0A91, 0A95 or 1N34A will be suitable. The purists still make their own diode detector with a 'cats whisker' and lump of galena, but modern diodes provide more stable and repeatable performance.

Headphones

The very old high impedance headphones are required for this circuit. A minimum of two kilohms is suggested. Medium impedance headphones (approx 600 ohms) will also work, but are less sensitive.

High impedance headphones have become difficult to obtain. Alternatives include:

1. Old-style telephone earpiece. Quite sensitive. Found in the old Telecom corded phones.

2. Crystal earpiece. These are sensitive, easy to obtain and inexpensive. You may need to connect a 100k - 470k resistor in parallel for it to work properly.

3. Piezo transducer. Believe it or not, these actually will work as an earphone. Some sizes even fit snugly in the outer ear in a similar manner to modern earpieces, such as used with mobile phones. The main drawback with transducers is their peaky audio response. Â In some cases it may be necessary to wire a 100k - 470k ohm resistor across the earphone connections for correct operation.

4. 1k to 8 ohm audio transformer and standard low-impedance headphones. Works well, but not as sensitive as a crystal earpiece.

5. Cheating! Use a transistor or IC amplifier kit to run a speaker. This approach eliminates the 'free radio' advantage of the crystal set, but provides louder reception in weak signal areas and allows speaker listening.

Coil and Coil former

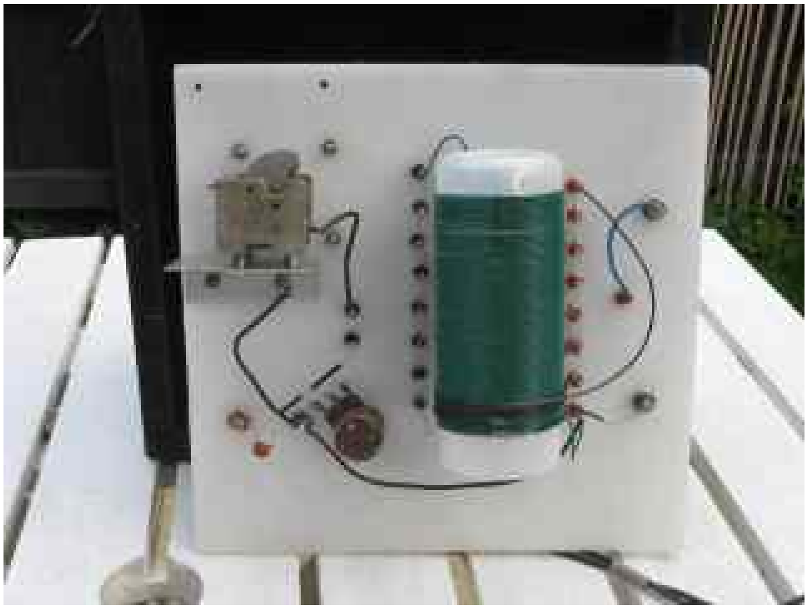
This needs to be a cylinder about 55 millimetres in diameter and 150 mm long. The length needs to be long enough to accommodate all ninety coil turns used, with enough left over for mounting to the front panel. Plastic pipe, shampoo container or similar will suffice. Though enamelled copper wire can be used for the winding, the prototype used thin plastic-covered stranded insulated wire.

Front panel

All parts are mounted on a 6mm-thick polyethylene chopping board, which forms the front panel. A hacksaw was used to cut the panel to fit inside the wooden case. Use the thinnest chopping board available so that the many screw-mounted sockets used can be fastened properly. The front panel pictured was cut to 240 mm square.

Case and handle

Use non-metallic material for the enclosure. The box used in the prototype was originally a speaker bought cheaply at a school fete. The lid (which held the speaker) was removed, and the rest of the box painted. The top carry handle is optional and came from a hardware store.



Construction

Commence construction once all components have been obtained. Plan how the parts will fit behind the front panel. The diagram and pictures above show the arrangement used in the prototype. The coil is fastened with stand-offs and the variable capacitor is screwed to an aluminium L-shaped bracket. 4mm binding posts with banana sockets are used for the antenna and headphone connections, and 2mm micro sockets for the coil tapping points.

Start by winding the coil. This consists of ninety turns of thin stranded insulated wire close wound on a plastic tube approximately 55 millimetres in diameter. A large number of tapping points are provided so that the user can vary the set's frequency coverage, and antenna and diode coupling. This makes it possible to obtain the best compromise between volume and selectivity for a particular station.

Figure Two shows the coil construction. Start from the earth end (identified as '0' in the diagram). Make two holes in the former to anchor the end of the wire. Wind six turns and then an extra half-turn. With a knife remove about 1cm of insulation, taking care not to cut the wire. Form the bare wire into a loop and lightly coat with solder. Do not apply excessive heat - the wire insulation easily melts. Wind another five and a half turns and make another tap. Repeat for the remainder of the coil until approximately ninety turns have been wound. Add more turns and taps if using a smaller variable capacitor than specified. Again make two small holes in the former to anchor the wire.

Place the completed coil aside and start work on the front panel. Mount the 4mm banana binding post terminals for the antenna, earth and headphones, as shown in Figure Two. Drill holes and mount the 2mm terminals for the coil taps and the antenna, diode, variable capacitor taps. The tuning capacitor can also be fastened at this time.

Two sets of screws and spacers can be used to mount the coil to the rear of the front panel. A 10mm separation between the coil and the panel is adequate. Solder in the various components and connecting wires as per Fig 2. Use insulated wire for the connections between the sockets and to the variable capacitor. Tinned copper wire can be used for the short links between the coil taps and the 2mm sockets. Use insulated wire for the three jumper leads. The jumpers should be sufficiently long to be able to make connections with all taps along the coil.

This completes the construction. The panel can now be inserted into the box. In the unit pictured, the front panel is recessed â€“ this protects the banana sockets and dial and makes the set more rugged. It also allows attachment of a hinged lid if required.

Parts List

* 10 â€“ 415 pF variable capacitor x1 (see text)

* 0.001 uF disc ceramic capacitor x1

* 1N60 germanium diode x1

* Vernier dial or drive x1 (optional)

* 2mm micro socket x19

* 2mm micro plug x6

* Banana socket (red) x2

* Banana socket (black) x2

* Insulated wire 20m

* Tinned copper or bell wire 1m

Other items: case and handle; polyethylene chopping board; Coil former â€“ 55mm dia, 150 mm long; screws, nuts, washers and spacers; mounting bracket for variable capacitor.

How it works

To receive signals, a radio circuit must perform three functions: selection, detection and reproduction.

The inductor and variable capacitor form a tuned circuit. The role of the tuned circuit is to select one of the many signals present at the antenna. The size of the inductor and capacitor determines the frequencies that can be tuned. The capacitor is made variable to allow the full range of AM broadcast band frequencies (531 to 1602 kHz) to be received.

The diode detector converts the selected radio frequency signal to an electrical current varying at audio frequencies.

The headphones convert this audio frequency energy to sound. The principle is similar to a relay â€“ the signal cause current to flow in a winding that forms an electromagnet. The magnetism generated vibrates the metal diaphragm, thus creating sound. Crystal earpieces perform the same function, but rely on the piezo-electric effect.

Unlike in a conventional radio, which uses amplifying devices such as transistors and integrated circuits, crystal sets are powered by the signal from the incoming station, so no batteries is required. If provided with an efficient antenna and earth, crystal sets can receive signals thousands of kilometres away.

Antenna and earth

A crystal set requires a wire antenna to operate properly. The longer and higher it is the better. A length of at least 10 metres in urban areas, and 20 â€“ 30 metres elsewhere should provide reception in most cases. The antenna should always be installed away from power lines for safety reasons and to reduce interference pick-up. An existing amateur or TV antenna can also be effective, especially if the coaxial feedline is used as part of the antenna. This is achieved by connecting both the outside and the inside of the coaxial connector to the receiver's antenna terminal.

An earth provides stronger signals, and is essential in remote areas. In homes with copper water pipes, this can simply be a lead to the nearest cold water tap. In newer homes, where plastic pipes are used, an outside ground stake can be used instead.

For long distance reception (hundreds or thousands of kilometres) more than usual effort needs to be taken when installing the aerial and earth. Reference One suggests a length of about 100 metres and a height of at least 12 metres. A series of buried radials is suggested for the earth, rather than the water pipe suggested above.

Operation

Connect antenna, earth and earphones. Install the three jumper leads. Set the capacitor tap to near the top of the coil (either the 78th or 90th turn) and the diode and antenna taps to approximately midway along the coil.

In a quiet room, adjust the tuning control and listen for a station. If several stations are audible, move the diode or antenna taps nearer the earth end (lower numbered turns) of the coil. This increases the set's selectivity and makes it possible to separate stations. In a capital city it should be possible to separate at least nine or ten stations. Optimum tap settings vary across the broadcast band â€“ lower frequency stations are often best received with higher tap settings. In rural areas volume is normally more important than selectivity, so the taps can be moved near the top of the coil.

Reception of AM operators on the 1.8 MHz (160 metre) amateur band is possible by moving the capacitor tap lower down the coil, to the 54th or 66th turn. Performance will be well down on a superhet or regenerative receiver, and SSB signals cannot be resolved. Whether you hear amateurs or not depends on your antenna system and the extent of activity from nearby operators. Here in Melbourne 160 metre AM activity includes the Monday to Saturday AM morning net starting at 11am.

In many areas there are narrowcast stations between the top of the official AM broadcast band and 160 metres. Because of their low power these stations will be weaker than the mainstream broadcasters. However these stations are excellent tests of your receiver and antenna system.

Video demonstrations of this project

Conclusion

A crystal set of moderate complexity has been described. It is the minimum required to provide good reception of local stations in urban and rural areas. However numerous refinements to increase sensitivity, selectivity or audio output can be made. These include:

1. Double tuned circuits (with variable coupling between them) to improve selectivity

2. Use of a tuned trap to null out interfering signals

3. Attention to the construction of coils to provide the highest possible Q

4. Addition of an impedance matching network to provide efficient power transfer between the antenna and the tuned circuit

5. Use of a large loop antenna for the coil to allow reception of signals without an external antenna and nulling of unwanted signals

6. Voltage doubler diode detector circuit using two diodes to increase volume

7. Use of DC bias (from a DC voltage applied to the diode) or RF bias (from a locally generated RF signal on the receiving frequency) to improve sensitivity, or, in the case of the latter, to provide CW and SSB reception.

8. Use of a Q multiplier to increase sensitivity and allow CW and SSB reception.

Should you decide to experiment with these changes, it would be desirable to keep this set as a reference and build a second receiver as a test bed for the experiments.

TECHNICAL AND THEORETICAL SPECIFICATIONS FOR WARP DRIVE TECHNOLOGY

FIELD OF THE INVENTION

[0001] The present invention relates to the use of technical drive systems which operate by the modification of gravitational fields. These drive systems do not depend on the emission of matter to create thrust, but create a change in the curvature of space-time, in accordance with general relativity. This allows travel by warping space-time, to produce an independent warp drive system.

THEORETICAL BACKGROUND OF THE INVENTION

[0002] The concept of gravity should be examined in the light of quantum gravity and in turn as a component of quantum physics itself. The fundamental minimal quantum of energy in quantum physics is Planck's constant; h. Thus in accordance with the energy equivalence formula $E=mc^2$, the fundamental minimum quantity of mass (m_q) can therefore be derived, from known constants by; $m_q=h/c^2$ (1). Taking this minimal mass, it is possible to show that the formation of all matter, the forces of nature and indeed space-time itself derive from this single quintessential quantity.

[0003] Thus if the number of quintessences in a system is; $n_q=m/m_q$: then the total Energy of the system is more logically given by, the energy of a single quintessence (h); directly multiplied by the number of quintessences (n_q) in that system, thus $E=hn_q=mc^2$ (1 a).

[0004] Furthermore, this minimal mass, termed quintessence, can form the basis of the existence of a quantum gravitational field in the form of a space-time lattice, from which quantum gravity may be derived from first principles. Furthermore, the conglomeration of these quintessences also accounts for the formation of the elementary particles and the forces acting between them, as in superstring theory. This concept explains the formation of matter and the forces of nature on a quantum mechanical basis and directly explains the existence of wave particle duality. Thus as $n_q=m/m_q$; the frequency of light and matter (f) is determined, directly, from the number of constituent quintessences. This leads automatically to the fundamental equation, derived from (1), $f=n_q=E/h$, where n_q is the number of quintessences, which leads directly to the frequency of both light and matter. This in turn leads directly to a Universal wave equation for matter and light $\lambda=c/\beta n_q=hc/\beta E$ (2), where β is the relative directional velocity, v/c. As the momentum, $p=\beta E/c$, then this equation also gives the standard de-Broglie wave equation, $\lambda=h/p$ in agreement with current theory and experiments.[1]

[0005] Using the Universal wave equation, the standard equation for special relativity, $m'=m_o/(1-\beta^2)^{1/2}$, derives from first principles. Also from these observations, a modified Dirac wave equation may be derived, $E\psi=(-j\beta\cdot\nabla+\beta m)\psi$ (2a), the results of which have been recently verified by a paper in which the orbitals of electrons were experimentally directly visualised.[2] Moreover, a fundamental equation for general relativity can be formulated, where G is the gravitational constant and r_q is the given radius of quintessence; $G=9r_q^2c^4/\lambda\beta E$ (3), such that the Universal wave equation is in direct agreement with general relativity.[3] Thus special and general relativity and quantum mechanics can be unified.

[0006] From here it is possible to proceed in a number of ways; the geometric structure of the electron and the forces of Nature may be derived from first principles and in turn the structure of the quarks, including the top and bottom, otherwise known as truth and beauty can be seen. Moreover, the presence of a space-time lattice results in an understanding of quantum EPR effects. By allowing a theoretical flow of energy through the space-time lattice it can be shown that:

[0007] Energy is not bound by space-time

[0008] Thus logically accounting for phenomena such as entanglement and quantum tunnelling. Quintessence can also be used to explain, logically, the inner physics of a black hole, the missing mass of the Galaxy, the continuing expansion of the Universe, Guth's inflationary theory and the Big Bang. Hence, it is now possible to understand the Universe, including space-time, matter and the forces of nature from the radius, mass and vibration of a single quantity, quintessence.

[0009] With this understanding of space-time, matter and the forces of Nature, and in particular gravity, it is possible to demonstrate that the modification of gravitational fields, and in turn the warping of space-time, can be technically readily achieved.

[0010] Using standard equations for special relativity, $m'=m_0/(1-\beta^2)^{1/2}$, it can be demonstrated that by differentially increasing the velocity of electrons, by applying a differential current, their mass can be increased in a specific way. In turn by increasing the mass of electrons, by general relativity, the number of gravitons emitted from these electrons can be modulated. By multiplying this effect using an ultracentrifugational device the differential graviton emission can be manifestly amplified. This in turn, in accordance with general relativity, will cause a change in the curvature of space-time.

[0011] This effective warping of space-time does not, of necessity, imply superluminal velocities, but does allow the creation of warp drive systems, which do not depend on the creation of thrust by the ejection of material as used in current space technologies.

Part I

Fundamental Laws of Physics

[0012] Quintessential Mass

[0013] The quantum physical, minimum component of energy is Planck's constant; h. To define the minimal component of mass, using the standard energy equivalence formula; $E=mc^2$, such a minimal mass (m_q) would be required to have the value equivalent to; $m_q=h/c^2$ (1). The total mass of a system (m) would then be; $m=m_qn_q$, where n_q is the number of these minimal units. Thence, the total energy of a system can be derived from the minimal energy; h, multiplied by the number of these energy units (n_q). Thus as, $E=mc^2$, then also $E=m_qn_qc^2$ and substituting $m_q=h/c^2$, the energy equivalence formula has the more logical formulation; $E=hn_q$ (1a). Thus the energy of a system is equivalent to the minimal energy unit; h, multiplied by the number of those minimal energy units (n_q).

[0014] Taking this minimal mass/energy, it is possible to show that all matter, the forces of nature and space time can be constructed from this single quintessential quantity. Moreover, using this quantity the laws of physics can be derived from first principles. Thus, a priori, all components of the physical universe, including space-time, can be constructed from this minimal mass component, termed quintessence.

[0015] Wave Particle Duality

[0016] If the presence of quintessence accounts for the structure of matter and if matter itself forms from the number of quintessences, then the frequency of matter and thus wave particle duality directly arises from first principles. Specifically the wavelength of matter derives from the vibration of quintessence from which it is constituted. Thus the frequency (f) and in turn the wavelength of light and matter is directly equivalent to the number of quintessences contained within it. We find that the actual frequency of light can be directly derived from first principles from the effective mass of the photon (m,) and thus by the number of quintessences (n_q) it contains.

[0017] Thus for light conventionally:

$$f=E/h$$

[0018] and if $E=mc^2$, and $h=m_q.c^2$, then

$$f=m_\gamma c^2/m_q.c^2$$

[0019] and

$$f=m_\gamma/m_q=n_q$$

[0020] Thus

$$f=n_q \tag{4}$$

[0021] Thus the formula for the frequency of light (E=hf) is now readily explained by the observation that the frequency is determined quite directly from the number of quintessences (n_q) within the photon.

[0022] The wavelength is thus also given by:

$$\lambda=c/f=m_q c/m_\gamma=h/p$$

[0023] We can now show that the frequency of matter also has the same derivation from quintessence, as has the frequency of light. The frequency of matter is again equivalent to the number of quintessences it contains. Thus the wave particle duality of matter itself can be explained by its composition from quintessence. The amount of quintessences contained within a electron sphere will depend on the number of quintessences constituting the electron and those passing through it as a result of its relative velocity β^2 (where $\beta=v/c$); effectively its relativistic momentum (p). The frequency will then be related to the total number of quintessences. Thus for matter,

$$f=\beta^2 n_q \tag{4a}$$

[0024] Thus it is possible to derive the conventional de Broglie wave equation for matter from first principles. Thus, as $\lambda=v/f$, we have:

$$\lambda=v/\beta^2 n_q \tag{5}$$

[0025] thus as $n_q=E/h$

$$\lambda=hc/\beta E \tag{2}$$

[0026] and as conventionally $\beta E/c=p$, then for matter:

$$\lambda=h/p$$

[0027] Provided that in the de Broglie equation, the momentum of the object is calculated using the relativistic mass, thus accounting for the total number of quintessences (n_q) in an object, this gives an accurate value for the wavelength of matter.[1]

[0028] Thus the wavelength of matter follows directly from its constitutents, quintessence. As matter is made of quintessence, similarly to light, its frequency depends on the number of quintessences (n_q) within it, travelling relative to the speed of light. Moreover, $\lambda=hc/\beta E$, underpins a fundamental relationship between wavelength and energy. Furthermore, this is mathematically the same as the term $\lambda=hv/\beta^2E$, giving a relativistic expression for the the wavelength of matter, from which the relativistic equations may be directly derived (see Wave Particle Duality and Relativity).

[0029] Wave Equations

[0030] The derivation of wave particle duality from first principles also now allows the derivation of a modified wave equation for matter.

[0031] To derive his wave equation Shrödinger commenced with the de Broglie equation using momentum (p). For lower energies the momentum of an electron is conventionally derived from the kinetic energy of the electron and the mass of the electron mo. Thus conventionally:

$$E_K=\tfrac{1}{2}mv^{1/2}\text{and } p=m_0v$$

[0032] Thus

$$E_K=p^2/2m_0$$

[0033] then

$$p=(E_K.2m_0)^{1/2}$$

[0034] and conventionally, the de Broglie equation can also be written as:

$$\lambda=h/p=h/(E_K.2m_0)^{1/2}$$

[0035] In turn the Shrödinger wave equation directly derives from the square of the above classical non relativistic term for kinetic energy:

$$\lambda^2=h^2/E_K.2m_0$$

[0036] thus

$$E_k=\frac{h^2}{2m}\cdot\frac{1}{\lambda^2}$$

[0037] As $E=E_k+V$

[0038] then

$$E\psi=-\frac{h^2}{2m}\cdot\frac{d^2\psi}{dx^2}+V\psi=jh\cdot\frac{d\psi}{dt}$$

[0039] However, the Shrödinger equation, may be refined by taking into account relativity. Thus the true values for the energy are given by the relativistic momentum (p).

[0040] A fundamental relativistic wave equation for ψ, and its logical derivation may now be developed through the concept of quintessence as a fundamental constituent of matter.

[0041] The amount of quintessences in the electron is determined by the number of quintessences forming the electron at rest, plus the amount of quintessences passing through it due to its relativistic velocity, which will determine the relativistic momentum (p) of a particle.

[0042] The frequency of matter can now be readily calculated from first principles to give a more accurate result. Thus as matter is made of quintessence, similarly to light, its frequency is equal to the number of quintessences (n_q) within it. The wavelength will depend on its velocity travelling relative to the speed of light and thus multiplied by the relative velocity compared to c ($\beta=v/c$);

[0043] Hence for matter as previously shown:

$$\lambda=v/\beta^2 n_q=hc/\beta E \tag{2}$$

[0044] And conventionally

$$E=(p^2c^2+m_0{}^2c^4)^{1/2}$$

[0045] Using these equations, we can now, also, reformulate the Shrödinger wave equation, which has the advantage that relativity can be treated in a quantum mechanical way. Thus if the wave energy of matter is defined as:

$$E_\lambda=\beta(p^2c^2+m_0{}^2c^4)^{1/2}/c^2$$

[0046] thus

$$E_\lambda=(\beta^2p^2/c^2+\beta^2m_0{}^2)^{1/2}$$

[0047] which in complex space generalises to

$$E_\psi=(-j\beta\cdot\nabla+\beta m)_\psi \tag{2a}$$

[0048] As the term $\alpha=e^2/hc.4\pi\epsilon_0$; also represents the ground state ratio of the velocity of the electron to c. Thus $\alpha=\beta=v/c=1/137$.

[0049] Thus, also

$$E_\psi=(-j\alpha\cdot\nabla+\beta m)_\psi$$

[0050] This is thus the standard relativistic equation that Dirac was able to construct from the Shrödinger wave equation. This relativistic equation can be derived from the modified wave equation (2). This takes into account the relative mass energy which the quintessential wave equation (2) contains.

[0051] Where importantly the term βm is the mass m, multiplied by the ratio of the relative velocity to light $\beta=v/c$, and the term a is also essentially the relative velocity of the electron.

[0052] The Dirac equation was an empirical formula which worked mathematically, nevertheless even Dirac admitted it was not logically understood. The importance of these equations (eq. 2, 2a) is that they show that the existence of quintessence allows the waveparticle duality of matter to be explained and mathematically derived from first principles, Thus the frequency of matter or even light is simply determined by the number of quintessences it contains.

[0053] Indeed, a recent publication in Nature has suggested that the direct visualisation of the orbitals of electrons shows that these are in very close agreement with theory. However, there is a significant departure from theory, in the interstitial molecular regions, suggesting that the higher velocities of the electrons obey the modified Dirac equation (2a).Thus these orbitals were in keeping with the modified Dirac equation, which itself may be derived from the wave equation above, $\lambda=hc/\beta E$ (eq. 2) (ref 2)

[0054] The Shrödinger wave equation will approximate to the correct values until v approaches c. Indeed the Shrödinger equation will give similar answers as that derived from equation (2a), under most experimental conditions.

[0055] However, equation 2 and its derivative (2a) may have advantages over standard Shrödinger theory with relativistic speeds. Furthermore, equation 2, conceptually shows that the wave particle duality of matter derives from the principle that the frequency of matter is directly equal to the number of quintessences it contains. Importantly it also mathematically allows relativity and quantum mechanics to be united.

[0056] With $v \cong c$, the modified Dirac equation (2a) will yield more accurate results, particularly compared with the Schrödinger equation. We also find that the equation $\lambda=hc/\beta E$ (2) is equivalent to the de Broglie wave equation, $\lambda=h/p$, provided we use the relativistic mass in the de Broglie equation. Given this, these equations yield accurate experimental results (ref 1).

[0057] Thus we find that the modified formulation of de Broglie wave equation $\lambda=hc/\beta E$ (eq. 2a) leads directly to a modified Dirac relativistic wave equation and is supported by recent experiments which measure the wavelength of matter and demonstrate the electron orbitals experimentally from these wave equations for matter (ref 1,2).

[0058] Wave Particle Duality and Relativity

[0059] From here it is possible to proceed in several ways using the relativistic wave equation (2). It is apparent that the reintroduction of the term for relative velocity into the wave equations will enable the reintroduction of special relativity into quantum mechanics. In particular we should now be able to derive the term $(1-v^2/c^2)^{1/2}$ as a special case of quantum mechanics.

[0060] Thus if:

$$\lambda=hc/\beta E \tag{2}$$

[0061] As $E=(p^2c^2+m_0{}^2c^4)^{1/2}$, squaring

$$\lambda^2=h^2c^2/\beta^2(p^2c^2+m_0{}^2c4)$$

[0062] Conventionally $p^2c^2=E^2v^2/c^2$

[0063] then

$$\lambda^2=h^2c^2/\beta^2(E^2v^2/c^2+m_0{}^2c^4)$$

[0064] Thus as $\beta^2=v^2/c^2$ and $m_0{}^2c^4{}^{=E}{}_0{}^2$, then:

$$\beta^4E^2+\beta^2E_0{}^2=h^2c^2/\lambda^2$$

[0065] hence

$$\beta^4E^2=h^2c^2\cdot\frac{1}{\lambda^2}-\beta^2m_0^2c^4$$

thus

$$\beta^2=\frac{h^2c^2}{\beta^2E^2}\cdot\frac{1}{\lambda^2}-\frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

-continued

As $E^2 =' m^2c^4$

$$\beta^2 = \frac{h^2c^2}{\beta^{2\prime}m^2c^4}\cdot\frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

Substituting $h = m_qc^2$

$$\beta^2 = \frac{m_q^2c^6}{\beta^{2\prime}m^2c^4}\cdot\frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

As $\mathrm{m}_q/'m = 1/n_q$(eq. 2)

$$\beta^2 = \frac{c^2}{\beta^2n_q^2}\cdot\frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

[0066] Thus if $f=\beta^2 n_q$ (eq. 7a);

$$\beta^2 = \frac{v^2}{f^2}\cdot\frac{1}{\lambda^2} - \frac{\beta^2m_0^2c^4f^2}{\beta^2E^2}$$

As $1/\lambda^2 = f^2/v^2$

$$\beta^2 = \frac{v^2}{f^2}\cdot\frac{f^2}{v^2} - \frac{\beta^2m_0^2c^4f^2}{\beta^2E^2}$$

Thus:

$$\beta^2 = 1 - \frac{\beta^2m_0^2c^4}{\beta^2E^2}$$

As $E^2 =' m^2c^4$

$$\beta^2 = 1 - \frac{m_0^2}{'m^2}$$

Hence

$$m_0/'m = (1-\beta^2)^{1/2}$$

Thus

$$'m = \frac{m_0}{\left[1 - \frac{v^2}{c^2}\right]^{1/2}}$$

[0067] Thus this derivation now allows relativity as a universal case of the quintessential wave nature of matter.

[0068] The original premises on which special relativity was based were: that the speed of light is a constant and that all observers are equal. As the speed of light has dimensions of length and time but not apparently of mass, the relativistic change in mass is not accounted for. Using quintessence logically and directly accounts for the relativistic mass changes.

[0069] Moreover, relativity can be derived from the de Broglie equation, and visa versa, directly, thus linking relativity and quantum mechanics by taking into account the existence of quintessence mass.

[0070] Hence, it is now possible to derive the relativistic equations for mass and in turn for space and time from the quintessential wave equation, thus deriving special relativity as a universal case of quantum mechanics and thus uniting special relativity and quantum mechanics. This now allows a further understanding of the nature of space-time.

[0071] The Space-Time Lattice

[0072] The understanding of the true nature of space-time and how it is formulated in three dimensions of real space is crucial. To simply assume that space-time exists, and thence not to question the nature of that existence, denies a deeper understanding of the universe.

[0073] In order to understand the nature of space-time itself, at the quantum level a further look at the nature light and the photon is necessary. Since Einstein's description of light as a particle (the photon) and the description of the photoelectric effect, the standard picture of light as simply a wave can, no longer be applied. If light was to exist as a photon, it could not exist in one dimension, as ordinary waves do, it would need to be three dimensional, with the addition of time. Let us suppose, in this case, that a photon is a three dimensional helical ringlet of light, travelling in the x vector, and spinning around the x-axis. Conventionally this ringlet has a radius; $r=\lambda/2\pi$. The ringlet itself would be vibrating in the y and z vectors. The vectors x, y and z would represent the photon, the substance of which, would be travelling in the x direction and oscillating in the y and z vectors, which would represent oscillatory energy. This in turn would allow it to act as a wave, and create oscillatory electromagnetic fields.

[0074] It is important to re-examine space-time itself in this light, this would have one directional vector with two vector dimensions of energy, one of capacitance and one of electrical permeability, thus accounting for the well known constants of free space; the permittivity of free space (ϵ_0) and the permeability of free space (μ_0) respectively. The vector dimension of direction x, would be the direction of travel and those "quintessences" travelling in an outwardly direction would account for none other than the expansion of the universe. Three of these quintessences would naturally constitute three dimensional visible space-time. These constituents of space-time would interact with the generations of the other vector dimensions reciprocally. Thus one quintessence would sweep out one vector of permeability and one vector of permittivity, through which the other two quintessences could travel, and vica versa, creating a three dimensional space-time lattice.

[0075] The permittivity of free space, (ϵ_0) which is equivalent to capacitance, would as with capacitance plates, be determined by the effective separation between quintessences. The permeability of free space (μ_0) is in fact a force, measured as $4\pi\times10^7$ N A^{-2}, would result from the force produced by the vibration of quintessence and would be dependent on the density of quintessence. Hence these two parameters would be reciprocal and thus the product of these two would therefore be a constant, which is recognised as none other than the speed of light.

$$c=(\mu_0.\epsilon_0)^{-1/2}$$

[0076] This space time lattice would in effect be created by quintessences travelling in all directions with a speed of c within the lattice. The quintessences of the space time latice would in effect produce a non-static ether. A non-static ether is fully compatible with special and general relativity. Indeed such an ether explains how space time can be curved as in general relativity. Furthermore, the existence of a non-static ether, was espoused by Einstein in his University of Leyden lecture on general relativity of May 5, 1920. In Einstein's own words;

[0077] "According to the general theory of relativity space without ether is unthinkable."(ref 4)

[0078] Recent evidence from a number of sources now strongly support the presence of this non-static ether, in the form of quintessence. An editorial from a major journal states "combined with other observations such as those of distant Supernova, the QMAP results corroborate the prevailing theory of inflation with the twist that the Universe is only one third matter (both ordinary and dark) and two thirds quintessence, a form of energy possibly inherent in empty space".(refs 5, 6, 7)

[0079] If we take into account the existence of quintessence and as such a three dimensional space-time lattice, matter which is intrinsically made of contituents of charge would interact with this lattice to produce the effects of mass. Mass would be perceived as a result of matter (whose constituent particles appear to contain charge) interacting with this lattice directly due to the inhibition of motion by the lattice's electrical permeability and permittivity vectors, which would form the existence of complex space. These quintessences would in the direction in the y and z vectors produce small vibrations of the order of the Planck length (10^{-35} m), whilst passing through the vectors of permeability and permittivity, thus producing the effects of mass.

[0080] The vibration would endow quintessence itself a (non rest) mass (m_q) equivalent, to the minimal mass of:

$$m_q = h/c^2 = 7.373\times10^{-51}\ \text{kg.sec} \tag{1}$$

[0081] The presence and magnitude of Planck's constant (h) and especially the speed of light (c) is thus explained. Indeed, the speed of light $c=(\mu_{0.}\epsilon_0)^{-1/2}$ is not in itself a fundamental quantity.

[0082] As the energy equivalence formula is $E=mc^2$, the minimal mass of a single quintessence, would thus be the minimal mass, h/c^2, hence again:

$$m_q = h[\mu_0.\epsilon_0] = h/c^2 = 7.373\times10^{-51}\ \text{kg.sec} \tag{1b}$$

[0083] or

$$m_q c^2 = h \tag{1c}$$

[0084] It is postulated by general relativity that the shape of space time itself can be altered, indeed the presence of the space time lattice now allows this to be altered by altering the density of quintessence. It is further clear that if quintessences underly the structure of the space-time lattice, they may also underly the structure of matter itself.

[0085] With regards a single quintessence, this passing through an energy vector of the space-time lattice would appear as a vibrating string. In a similar way to string theory, the conglomeration of these quintessences would produce the constituents of ordinary matter. Thus the general equation for the number of quintessences (n_q) in an object of mass (m) would be

$$m/m_q = n_q$$

[0086] The mass of the electron (m_e) for example, would be directly determined by the number of quintessences in the electron, multiplied by the mass of quintessence.

[0087] Quintessence and Complex Space

[0088] Quintessence is postulated to constitute the fundamental nature of space-time. Three quintessences each travelling in their respective x vectors at 90° to each other would create three dimensional real space-time. These quintessences would in the direction in their respective y and z vectors produce small vibrations of the order of the Planck length (10^{-35} m), this would create the vector dimensions of permeability and permittivity. The result would give space-time 9 dimensions of space as in superstring theory. However, unlike superstring theory the six hidden dimensions would not be "curled up so as to be so small as to be invisible" these six dimensions would be present in complex space. Thus, only three of these dimensions would represent ordinary three dimensional particulate space time i.e. three dimensional objects. The other six dimensions produced by the vibrations of quintessence would form complex space.

[0089] The mathematics of complex space, using imaginary √−1 or (j) numbers, is assumed in the standard formulation of the Shrödinger wave equation. Thus the presence of complex space is an integral part of quantum mechanics.(ref 8)

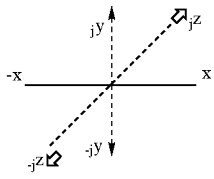
$$-\frac{h^2}{2m}\cdot\frac{d^2\psi}{dx^2} + V\psi =_j h\cdot\frac{d\psi}{dt}$$

[0090] The mathematics of complex space is also an essential and integral part of the principles and application of modern electronic and control engineering. Indeed it has been well recognised for some time that each direction vector in electronic engineering can , be associated with complex vectors.(ref 9)

[0091] As this complex space consists of the vectors of permittivity and permeability it would only be "felt" by charged particles as in the electron. Nevertheless, as all particles are fundamentally composed of charged particles the effects of complex space would be felt by endowing these particles with mass and in turn kinetic energy.

[0092] In conventional complex space, a 2 dimensional Cartesian Argand diagram is mathematically used. However, in order to formulate the equations for particles a three dimensional Argand diagram is essential. This will have three dimensional vectors, one real vector and two imaginary vectors. Three of these diagrams will be required to fully describe the nature of particles, each with a real vector in the x, y and z vectors, respectively. Nevertheless, in the instance below the real vector is the x vector and the two imaginary vectors are given by ($_j$y, $_j$z)

The Three Dimensional Argand Diagram



[0093] The Three Dimensional Argand Diagram

[0094] The beauty of a three dimensional Argand diagram is that the complex conjugate (i.e. the mirror image which confers mathematical reality on the coordinates) is formed by the value of the minus coordinate in the other complex vector dimension. Thus the complex conjugate of $(c_x^{1/2}+{}_jc_y^{1/2}+{}_{-j}c_z^{1/2})$ is $(c_x^{1/2}+{}_jc_y^{1/2}+{}_jc_z^{1/2})$. These two sums when multiplied thus give a real number solution.

[0095] Furthermore it is clear that nine dimensions of space time are necessary in the general relativistic equations. By including complex space we thereby create the nine dimensional spacial metrictensor and the metric energy tensor of matter necessary for computations for general relativity (see quantised general relativity pp 34-35). From here we can begin to understand the true structure of matter.

[0096] Energy and the Space-Time Lattice

[0097] The presence of numerous experimental data for quantum tunnelling(refs 10, 11, 12, 13) and indeed the recent observations by Nicholas Gisin, on the entanglement of distant photons now returns us to EPR experiments.

[0098] Using the quintessential modification of the de Broglie wave equation, gives us an insight into these teleportation and EPR effects.

[0099] As

$$\lambda=hc/\beta E \tag{2}$$

[0100] and

$$E=hn_q \tag{1a}$$

[0101] then

$$\lambda=c/\beta n_q \tag{2b}$$

[0102] Importantly, as indicated by equation (2b), energy having no quintessence; would have a wavelength of infinity. Specifically pure energy containing no quintessences, would have a lambda of infinity. According to quantum mechanics an infinite wavelength would result in the probability of that energy being anywhere. As energy itself has no electrical charge it would not be impeded by the permittivity and permeability of the three dimensional space-time lattice. Moreover, energy would not be detectable in three dimensional space-time, unless it interacted with matter, as in the EPR experiments. Indeed, energy is not observed when not bound to any form of mass or particle. Thus equation 9d, takes us to our original assertion

[0103] Energy is Not Bound by the Space-Time Lattice

[0104] Thus, as the EPR experiments suggest the existence of energy separate from matter and thus separate from the three dimensional space-time lattice, it is interesting to find that experiment suggests the existence of free energy in a continuum separate from space time to produce the effects of quantum teleportation.(refs 10, 11, 12, 13)

[0105] This is not, however, teleportation across an additional dimension, this is a term to describe in partially familiar terms the dissociation of energy from the three dimensional space-time lattice. As time is inextricably linked to each dimension of space, the effects of energy would be inextricably linked to the events, such as the creation of virtual particles, we see interacting within space-time.

[0106] It is unlikely that observers have any direct day to day experience to explain quantum events. Nevertheless, quantum physics may have given us a window into the hitherto hidden workings of the Universe. Thereby, the mystery of the uniformity of the Universe, across distances which the speed of light could not apparently traverse, is readily explained by the fact that the free energy contained in the Universe is not bound by the space-time lattice.

[0107] In the case of light, due to the exceedingly small masses involved, there would be relatively easy exchange of matter with free energy within a photon. This would make the photon the ideal experimental tool to look for energy which is not bound by matter and in turn energy which is not bound in space-time. Indeed, very recently Furusawa et at. have reported to have observed the transference of energy as photons from A to B, without those photons traversing space-time(ref 10). This finding which has been supported using other experimental techniques(refs 11, 12, 13,), is very important as it suggests the existence of such a quantum continuum.

[0108] We have already seen strong experimental data using photons(ref 10), atomic spins and other data for quantum teleportation which have recently been published (refs,11, 12, 13), which support these findings. According to the above equations the teleportation would vary in a predictable fashion, as with photons, in line with the wavelength of the light used, relative to the size of vibration of quintessence. As regards matter, the results do confirm that the effect of quantum tunnelling is indeed dependant on the wavelength of matter and the size of that matter(ref 10).

Part II

Particle Physics

[0109] Electron Structure

[0110] Understanding the electron is fundamental to the understanding of the elementary particles. The hidden nature of the electron may recently have been revealed through observations by Horst Stormer, Daniel Tsui and Robert Laughlin for which a Nobel prize has recently been awarded. They describe a quasi electron particle of charge ⅓e. This has been described on a quantum basis as a vortex of energy, bound as a quasi particle in one dimesion x, but not bound in the other two dimensions y and z, allowing dispersion in space-time as a vortex. What is more intriguing are the experimental conditions in which this occurs. First of all a two dimensional electron gas is created and held between two capacitance plates. A magnetic force is then applied in the remaining dimension, virtually creating a one dimensional passage through which only a quasi electron appears to be able to pass.(refs 15, 16)

[0111] Given the presence of charge of ⅓e, then three of these quasi electrons could form an entire electron in three dimensional visible space time. Nevertheless, each would have energy and hence a wave function which would be present in the other vectors. This electron could thus follow the probability functions as described by the Shrödinger wave equation for ψ (otherwise termed as "essence" by Shrödinger)

[0112] If the mass of the electron (m_e) is constituted from quintessence, using the formula:

$$m_e/m_q=n_q$$

[0113] Then an electron would be constituted from:

$$9.11\times10^{-31}\ \text{kg}\div7.373\times10^{-51}\ \text{kg.sec}=1.236\times10^{20}\ \text{quintessences/sec.}$$

[0114] Thus taking into account the mass-energy content of quintessence (m_q) it is independantly possible to derive the magnitude of the charge of an electron (e) using the following equation.

$$e=[m_q\epsilon_0/\tfrac{4}{3}\pi hc]^{1/2}=1.61\times10^{-19}C$$

[0115] This is in close agreement with the experimentally observed charge on the electron of 1.602×10^{-19} C.

[0116] Interestingly substituting $m_q=h/3c^2$ in the above equation we have:

$$e=[\epsilon_0/3(\tfrac{4}{3}\pi c^3)]^{1/2} \tag{6}$$

[0117] This can also be written as

$$e=\left[\frac{\varepsilon o}{3(4/3\pi c^3)}\right]^{1/2} \tag{6a}$$

[0118] Equation (6) has a number of very special implications, if re-examined, firstly three of these quasi electron spheres appear to to be required to constitute the charge of the electron . More intriguingly, it indicates that the charge is related to the volume of a sphere with an apparent radius of c. Thirdly it indicates that the square of the charge of an electron (e) is proportional to the permittivity of free space (so). The charge given from equation (3) is in close agreement with the measured charge of the electron. Furthermore a more exact value for the charge of the electron (to seven decimal places) can be deduced by taking into account the gravitational field of the Earth (see Gravity and the Charge of the Electron). Furthermore the charge of the electron (e) can now be derived from first principles. Thus, equation (3) corroborates the evidence that the electron is indeed composed of three quasi electrons in keeping with recent experimental findings.(ref 16)

[0119] The significance of the electron, composed of three spheres each with a radius of c, is not immediately clear, but can be understood if the frequency of rotation of the electron is taken into account. Thus if the diameter of the electron was approximately 10^{-19} m, then its spin would need to be $1/c.10^{-15}$ m$\approx10^{6}$ cycles/sec. Thus given a very high rotation rate an electron could have an effective radius of 1/c and still occupy subatomic sizes. Indeed these observations might be used to estimate the rate of rotation of the quasi electron and its size (see Appendix 1).

[0120] With regards a single quintessence, this passing through an energy vector of the space-time lattice would appear as a vibrating string. In a similar way to string theory, the conglomeration of these quintessences would produce the constituents of ordinary matter. The electron, for example, would be constituted from approximately 1.236×10^{20} quintessences.

[0121] The dimensions of the equation for the electron can be readily resolved by considering each of the three vector dimensions. The exact dimensions of the equation need to be considered in the light of the nature of space-time itself. These dimensional equations help explain the nature of matter. Indeed the equation for the electron may be necessary for the full understanding of gravity, this is also fully addressed (Appendix 1, Dimensional Equations)

[0122] Complex Space and Electron Structure

[0123] The presence of complex space also now further explains the conformation of the the electron, and its formulation at the quantum level, and the presence of particles, anti-particles and their spin up and spin down characteristics.

[0124] Indeed the short form equation for the charge of the electron (−e) can now be rewritten as a metric tensor with three dimensions in real space and six in complex space.

[0125] Thus if three of the x, y and z vectors are in real space and six vectors in complex space, where c is the speed of light in the real space vector, ${}_jc$ is the speed of light in the complex vector and ${}_{-j}c$ is the complex conjugate of ${}_jc$, thus the electron can be mathematically represented by the equation:

$$-e=\varepsilon_{qe}/(4/3\pi)^{1/2}\cdot\begin{matrix}(c_x)^{1/2} & \cdot(jc_y)^{1/2} & \cdot(-jc_z)^{1/2}\\ + & + & +\\ (-jc_x)^{1/2} & \cdot(c_y)^{1/2} & \cdot(jc_z)^{1/2}\\ + & + & +\\ (jc_x)^{1/2} & \cdot(-jc_y)^{1/2} & \cdot(c_z)^{1/2}\end{matrix} \tag{7}$$

[0126] Which now elegantly gives the real number solution

$$e=\epsilon_{qe}/3(\tfrac{4}{3}\pi c^3)^{1/2}$$

[0127] Where ϵ_{qe} is given as the permittivity of free space for a single quasi electron (see appendix 1). Equation 4 represents a "complex" tensor

[0128] Whilst the two dimensional Argand diagram has four quadrants, the three dimensional Argand diagram has eight cubic sectors. Two of these cubic sectors are diametric opposites and can represent "real" particulate objects. These have the primary coordinates x, y, −z; as in the electron described above, and the −x, −y, z, with the real vector x now having a minus sign. These two "real" cubic sectors, therefore, mathematically represent particles and their anti-particles.

[0129] The mathematical presence of the two primary diagonal mirror images (x, y, −z and −x, −y, z) now allow the introduction of the concept of antiparticles. This extension of the maths into a three dimensional Argand diagram thus results in the automatic formulation of the maths of anti-particles. Thus the charge of the positron (${}^+$e) is formulated by the shortened form equation, where the real vectors now each have the minus sign, and therefore exist in the −x, −y, z sector of the three dimensional Argand diagram.

$$e=\varepsilon_{qe}/(4/3\pi)^{1/2}\cdot\begin{matrix}-c_x^{1/2} & \cdot_{-j}c_y^{1/2} & \cdot_j c_z^{1/2}\\ {}_jc_x^{1/2} & \cdot -c^{1/2^y} & \cdot_{-j}c_z^{1/2}\\ {}_{-j}c_x^{1/2} & \cdot_j c_y^{1/2} & \cdot -c_z^{1/2}\end{matrix} \tag{8}$$

[0130] The three dimensional Argand diagram also accounts for chirality and indeed the up and down spin of the electron. There are two other "real" primary coordinates in the Argand diagram, these are themselves the partial mirror images of the above coordinates (i.e. x, −y, z and −x, y, −z).

In particular the y axis is of the opposite sign, thus in particles the y axis is in the downward direction, to form down spin particles and in anti-particles in the up direction, to form the antiparticle The up spin electron is given by eq. 8 and hence the down spin electron $(-e|\downarrow \leqq)$ is given by the equation

$$-el\downarrow\rangle = \varepsilon_{qe}/(4/3\pi)^{1/2} \cdot \begin{matrix} c_x^{1/2} \cdot_{-j} c_y^{1/2} \cdot_j c_z^{1/2} \\ {}_j c_x^{1/2} \cdot c_y^{1/2} \cdot_{-j} c_z^{1/2} \\ {}_{-j} c_x^{1/2} \cdot_j c_y^{1/2} \cdot c_z^{1/2} \end{matrix} \tag{9}$$

[0131] Thus the three dimensioanl Argand diagram accounts directly for the presence of antiparticles and the spin up and spin down particles seen in nature. It also accounts for the necessity of the electron to form a square root spherical object, as complex space depends on $\sqrt{-1}$, otherwise known as j.

[0132] Electron Pairing and Superconductivity

[0133] As the quintessences making up the electron are in a square root conformation, each of these quasi electrons would have a tendancy to pair to form an entire sphere.

[0134] The square root sphere structure of electrons with up and down spins can now superimpose to produce a complete sphere of varying extents. This produces electron pairing as seen at the atomic and molecular levels. It also accounts for the Pauli exclusion principle. This pairing thus accounts for the reactivity of the valence electrons and the electron probability densities, which in turn accounts for the existence of chemistry.(ref 8)

[0135] Furthermore, it is possible to account directly for superconductivity from first principles. For if both the complex and real vectors of the electron combine completely, the product of an up and down spin electron form a perfect superimposed sphere with radius c, with a charge of 2.59×10^{-38} Coulombs, denoted by the formula:

$$e^2 = \frac{\varepsilon o}{3(4/3\pi c^3)} = 2.59\times10^{-38} C \tag{6b}$$

[0136] As with standard superconducting theory, superconductivity can be explained by the formation of "Cooper" electron pairs, where the electrons are forced to pair by the presence of positve crystal charge in particular formation, at supercooled temperatures. In addition the electron pair now forms a stable entity whose angular momentum cancels.(ref 8)

[0137] It additionally becomes clear that the charge of two seperate electrons (2e) is 3.2×10^{-19} C, but the charge of the combined electrons (e^2) is 2.59×10^{-38} C. This electron pair thus appears to have 19 orders of magnitude less charge than the electron and in turn 19 orders of magnitude less resistance. It is this effective reduction in charge and in turn resistance which may account for superconductivity. When observed directly any electrical interaction with the Cooper electron pair will, however, result in the release of the full charge of both electrons, so that the full electrical charge put in will be equal to that coming out of the apparatus.

[0138] The Fine Structure Constant

[0139] Intruiginty from our knowledge of the electron we can further define the term α, the fine structure constant; from the structure of the electron. Thus as the standard term $\alpha=e^2/hc.47\pi\epsilon_0$; substituting the term $e^2=\epsilon_0/3(4/3\pi c^3)$ (eq. 6) and $h=m_q c^2$ (eq. 1) we find:

$$2\pi/\alpha=m_q[3(4/3\pi c^3)]^2$$

[0140] *or

$$2\pi/\alpha=m_q e^4/\epsilon_0{}^2$$

[0141] For brevity we may represent the quasi electron structure as $(4/3\pi c^3)=\Theta$; to signify its threefold symmetry, thus

$$2\pi/\alpha=m_q[3\Theta]^2 \tag{10}$$

[0142] Indicating that the fine structure constant of the electron (α) is indeed related to its dimensional structure. Again taking into account the effects of gravity the fine structure constant can be derived from first principles to nine decimal places (see Gravity and the Charge of the Electron).

[0143] Fundamental Forces and Particle Structure

[0144] In order to understand the fundamental forces and the nature of fundamental particles, an overview is required. Thus, there are three major forces; strong, electro-weak and gravity, each mediated by three force particles the gluon, photon and graviton respectively. These in turn, influence three types of particle, the quark, lepton, and by general relativity space-time itself. Each of these are composed of particles with multiples of charge of ⅓, which are themselves in three generations, and are present in three dimensions of real space. It is important that a comprehensive view of nature explains this threefold symmetry.

[0145] Using the Standard Model of particles, it is well accepted there exist quark particle charges of −⅓, −⅔ and +⅓ and +⅔ in quarks and anti-quarks. Given that each particle is made up of three quarks the presence of these fractional charges support the association of the fractional charges in this way to form three dimensional charged particles. In stable particles each of the three quarks would have a vector in one dimension, giving the three quarks together an existence in three dimensional visible space time. The particles that bind the quarks (gluons) are themselves required, in stable particles, to have three different colour charges, one colour in each dimension, for the particle to exist in three dimensional space-time. Furthermore, there are three generations of quarks (and indeed leptons).

[0146] The Standard Model (or a modification of this) and in particular the observation of quarks and indeed quasi electrons with fractional charge of ⅓ and ⅔ in both cases, indicates that particles are constituted from the equivalent of three of these quasi particles to form an electron and quarks to form baryons. In the normal three dimensions the energy would be carried by the particle, However, because each particle is constituted of three quasi particles and in each quasi particle or quark one visible dimension would be the direction vector, in the other two hidden dimensions of each vector the waves would carry energy. Thus each particle would be associated with vibration, which would account for wave particle duality and Heisenbergs uncertainty principle in three dimensional visible space-time.

[0147] These observations lead us directly to the previous postulate that the structure of the electron is composed of none other than three (root) spheres, and that this equation for the electron allows the determination of the charge of the electron from first principles, thus:

$$e=\frac{\varepsilon 0^{1/2}}{[3(4/3\pi c^{3})]} \tag{6}$$

[0148] In addition the mass of the proton (m_p) can be directly calculated from the ratio of the mass (m_e) of the electron, given by the equation:

$$m_e/m_p=5.45\times10^{-4}=3(\pi/c^{1/2}) \tag{11}$$

[0149] Strictly we should write, $m_e/(m_p+m_e)=3\pi c^{1/2}$; which is much more elegant.

[0150] Which now gives

$$m_e/m_p=1/(c^{1/2}/3\pi-1)=5.4462\times10^{-3}$$

[0151] This is in very close agreement with the experimentally derived ratio of the proton to electron masses which is also; 5.4462×10^{-3}

[0152] Thus the correlation factor between theory and experiment has a maximum error <0.00001 (ref 17)

[0153] If we combine equation 3: $e=[\epsilon_0/3(4/3\pi c^3)]^{1/2}$ and equation 13: $m_e/m_p=3(\pi/c^{1/2})$ the positive charge of the proton (e_p) is given by:

$$e_p=[\epsilon_0/3(4/3\pi c^3)]^{1/2}\times m_e.3(\pi/c^{1/2})/m_p=e \tag{12}$$

[0154] The stable nuclear proton conformation can thus be represented by the short form equation:

$$p=3^{+}(4/3\pi c^3)^{1/2}.3(\pi/c^{1/2}) \tag{13}$$

[0155] This forms a stable 3×3 conformation as with the stable electron structure.

[0156] Importantly the term $(\pi/c^{1/2})$ is the 90° solution to the Shrödinger wave equation for an electron confined in a space with radius c!(ref 8)

[0157] Thus the standard equation for an electron confined in a one dimensional box is given by:

$$E\psi(x)=-\frac{h^2}{2m}\frac{d^2\psi(x)}{dx^2}$$

[0158] If the one dimensional box has a length 2L the quantum amplitude (A) can only be non zero between x=0 and X=2L and the standard solution for the amplitude is none other than:

$$A=(1/L^{1/2})$$

[0159] Thus in one dimension the standard solution to the Shrödinger wave equation is:

$$\psi(x)=(\pi/L^{/12})\sin x/L$$

[0160] Thus not only is the electron charge derived from the equation for three spheres each with a radius of c (eq. 3); but the proton mass and charge can also be derived from the standard solution to the Shrödinger wave equation for a an electron confined in a space of radius c!(ref 8)

[0161] The term $(\pi/c^{1/2})$ itself would thus most logically represent the gluon which is present in the proton. These gluons would bind the quasi electrons together to form the fundamental particles

[0162] The masses of all the known particles, including the up and down quarks, the W boson, the muon, charm, strange, the tauon, truth and beauty can thus also be derived from first principles in this fashion, and have the quasi electron as their basic constituent particle (see Appendix 1).

[0163] Thus the structure of the muon (μ) can also be derived from the ratio of the mass of the electron (m_e) and the mass of the muon (m_μ):

$$m_e/m_\mu=4.7\times10^{-3}=/c^{1/3}$$

[0164] Thus

$$[\mu=\epsilon_0{}^{1/2}.m_e/m_\mu.3^{-}(4/3\pi c^3)^{1/2}.(\pi/c^{1/3})$$

[0165] Where the charge of the muon is in this equation equivalent to that of the electron e. In this case $(\pi c/^{1/3})$ can be considered to represent a specific high energy photon. Thus the structure of the muon, written in short form is:

$$\mu=3^{-}(4/3\pi c^3)^{1/2}.(\pi/c^{1/3}) \tag{14}$$

[0166] Moreover the structure of the tauon can be calculated from the ratio of the mass of the electron and that of the Tauon (1.79 Mev);

[0167] Thus

$$0.511\ \text{Mev}/1.79\ \text{Gev}=2.85\times10^{-4}$$

$$m_e/m_\tau=(\pi/c)^{1/3}.(\pi/c)^{1/9}=2.85\times10^{-4}$$

[0168] As the charge of the tauon is equivalent to the charge of the electron, hence the structure of the Tauon is given by the above equation

$$e_\tau=\epsilon_{qe}.m_e/m_\tau.3^{-}(4/3\pi c^3)^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9}=e$$

[0169] This equation accurately predicts the charge −1; and mass of the Tauon (~1.78 Gev)(ref 1). Thus the structure of the Tauon can in short form be given by the equation

$$\tau=-3(4/3\pi c^3)^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9} \tag{15}$$

[0170] Furthermore a more exact value for the mass of the muon and tauon can be deduced by taking into account the gravitational field of the Earth (see Gravity and the Charge of the Electron pg. 17) in a similar way to identifying the exact charge of the electron. In addition it may be necessary to take into account a possible mass value of the neutrino to arrive at a precisely accurate mass value of the muon and tauon. Nevertheless, the mathematical proof of these short form equations lies in the fact that they can very closely identify the charge and the masses of these particles, from first principles, as in equations (6, 13-27, see Appendix 1).

[0171] Overall the mathematical geometrical structure of all the particles can be derived from the quasi electron, which is in turn derived from quintessence. Thus, the short form particle structures can now be derived from first principles. This includes the quasi electron (qe) and electron (e), from which the quarks (u,d) and in turn the stable proton (p) and stable neutron (n) and alpha particle (α) respectively are derived. The general structure of the force carrying bosons the photon. (g) and the gluon (γ) and the intermediate vector boson (W) can be given. It will also intriguingly be possible to derive, according to their generation, the structure of the strange (s) charm (c), beauty (b, or bottom) and truth (t or top) quarks directly from the structure of the muon (μ) and Tauon (τ) respectively.

[0172] Using the term $\Theta=(\frac{4}{3}\pi c^3)$, where, –/+ represents the charge of the quasi electron, we find:

[0173] 1st Generation:

$$q_e={}^{-}\Theta^{1/2} \tag{6c}$$

$$e=3^{-1/2} \tag{6}$$

$$d={}^{-}\Theta^{1/2}.3(\pi/c^{1/2}) \tag{16}$$

$$u=2^{+}\Theta^{1/2}.3(\pi/c^{1/2}) \tag{17}$$

$$s={}^{-}\Theta^{1/2}.3(\pi/c)^{1/2} \tag{18}$$

[0174] 2nd Generation

$$\mu=3^{-}\Theta^{1/2}.(\pi/c^{1/3}) \tag{14}$$

$$c=2^{+}\Theta^{1/2}.(\pi/c^{1/3}).(\pi/c^{1/4}) \tag{19}$$

$$b={}^{-}\Theta^{1/2}.(\pi/c/^{1/9}).(\pi/c)^{1/4} \tag{20}$$

[0175] 3rd Generation

$$\tau=3^{-}\Theta^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9} \tag{15}$$

$$t=2^{+}\Theta^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9}.(\pi/c)^{1/4} \tag{21 }$$

[0176] Particle Gluons (g):

$$g_1=(\pi/c^{1/2}) \tag{22}$$

$$g_2=(\pi/c)^{1/2} \tag{22a}$$

$$g_3=(\pi/c^{1/4}) \tag{22b}$$

$$g_4=(\pi/c)^{1/4} \tag{22c}$$

[0177] Particle Photons (γ):

$$\gamma_1=(\pi/c^{1/3}) \tag{23}$$

$$\gamma_2=(\pi/c)^{1/3} \tag{23a}$$

$$\gamma_3=(\pi/c^{1/9}) \tag{23b}$$

$$\gamma_4=(\pi/c)^{1/9} \tag{23c}$$

[0178] Intermediate Vector Boson ($W^{+/-}$):

$$W^{+}=3^{+}\Theta^{1/2}.2(\pi/c^{1/6})^6 \tag{24}$$

$$W^{-}=3^{-}\Theta^{1/2}.2(\pi/c^{1/6})^6 \tag{25}$$

[0179] Stable* Proton:

$$p=3^{+}\Theta^{1/2}.3(\pi/c^{1/2}) \tag{13}$$

[0180] Stable* Neutron:

Stable* Neutron:

$$n=\begin{matrix} {}^{+}\Theta\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot{}^{-}\Theta\uparrow^{1/2} \\ {}^{+}\Theta\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot{}^{-}\Theta\uparrow^{1/2} \\ {}^{+}\Theta\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot\Theta^{-}\uparrow^{1/2} \end{matrix} \tag{26}$$

[0181] Alpha particle (α):

Alpha particle (α):

$$\alpha=\begin{matrix} [3^{+}\Theta]\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot[3^{-}\Theta]\uparrow^{1/2} \\ [3^{+}\Theta]\uparrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot[3^{+}\Theta]\downarrow^{1/2} \\ [3^{-}\Theta]\downarrow^{1/2}\cdot 2(3\pi/c^{1/2})\cdot[3^{+}\Theta]\uparrow^{1/2} \end{matrix} \tag{27}$$

[0182] The mathematical proof for these structures and their decay mechanisms is lengthy and is thus fully contained in Appendix 1. All the particle structures are accurately mathematically defined by the masses of these particles.$^{(\text{ref }17)}$

[0183] The structure of these particles all contain the quasi electron and thus the metric tensor structure necessary in the formulation of the gravitational equations is sustained. The respective forces created by the gluon and the photon are important as they tell us the behaviour of matter and also lead to the likely structure of the graviton

[0184] Particle Spin and Size

[0185] The significance of the electron, composed of three spheres each with a radius of 1/c, is not immediately clear, but can be understood if the frequency of rotation of the electron is also taken into account. Knowing the structure of the electron has led us to deduce its charge and thus may lead us estimate its size and spin. Thus these observations might be used to calculate the radius and rate of rotation of the electron.

[0186] Let us suppose, that nature is truly beautiful, and that the radius of the fundamental quasi electron is indeed 1/c, and in turn the radius was balanced by the velocity of rotation 2π/c. This can be directly confirmed mathematically by taking into account the known spin of the electron, h/4π. Thus the actual spin of the electron may be calculated form the known energy of the spin.

[0187] The radius of the electron is not up till now known, but the radius of a quark has been estimated, and this is the radius derived from deep inelastic collisions of the proton. These estimates reveal a radius of approx. $r_p=1.18\times10^{-15}$ m.$^{(\text{ref }13)}$ This value may be used to assist in confirming the spin of the proton in revolutions per sec. (revs) and in turn the spin and size of the electron. Firstly we may proceed to estimate the spin of the proton. Thus as h=E.t (Joules×sec) and E.t=F.d.t (Joules×sec), then the spin;

$$h/4\pi=F.d.t \tag{28}$$

[0188] As F=ma, where $a=(\text{revs. }2\pi)^2 r_{qu}$ and m=the mass of the proton, then

$$h/4\pi=m(\text{revs}.2\pi)^2 r_p.\text{d.t}$$

[0189] The actual distance (d) travelled in a circle of half integer spin in 1 second is: $\text{revs}.\pi r_p$, thus:

$$h/4=m(\text{revs}.2\pi)^3 r_p^{\,2}/2$$

[0190] Hence:

$$\text{revs}={}^3\surd[h/m(2\pi)^4 r_p^{\,2}]$$

[0191] Taking the effective mass the proton as 1.6726×10^{-27} kg, then the rate of spin of the proton in revolutions/sec is:

$$\text{revs}=5.65\times10^{6}\text{ cycles/sec}$$

---

* Stable nucleonic neutron and proton conformations differ slightly from the Standard Model, this is due to the sharing of quasi electron and quasi positron particles within the nucleus, which allows stabalisation of these particles by the formation of stable 3x3 structures. The Standard conformations which describe non-nucleonic neutrons and protons are additionally given in Appendix 1.

[0192] From the frequency of the specific rotation of the proton, given the half integer spin associated with the proton, we can thus mathematically confirm the relationship between the radius of a particle and its spin:

$$r_p \times \text{revs}/2 = 1/c \tag{29}$$

[0193] Furthermore, the fundamental radius of 1/c seen in geometric structure the quasi electron, is also reflected in the rotation rate and radius for the proton, thus as above $1/c \div \frac{1}{2}\text{revs} = 1.18\times10^{-15}$ m. Moreover, this means the actual half integer velocity of rotation is none other than 2π/c in metres/sec. So that the particle is in harmonic balance.

[0194] Using the fundamental formula h/4π=F.d.t, it is possible to obtain accurate estimates of the radius and spin rates of the electron, or indeed any particle, using the same principle of harmonic balance. Using the formula:

$$\text{revs} = {}^3\surd(h/m\ (2\pi)^4 r_e^{\,2}]$$

[0195] It appears there are two unknowns, the radius if the electron and its revolution rate, however, in accordance with the equation, $r_p = 2/c.\text{revs}$, which gives the revolution rate of the proton, the same principle may also be used for the electron, by substituting $r_e = 2/c.\text{revs}$, such that:

$$\text{revs} = hc^2/4m_e(2\pi)^4 \tag{30}$$

[0196] Taking the mass of the electron 9.109382×10^{-31} kg, the rate of revolution of the electron is:

$$\text{revs} = 1.048\times10^{10} \text{ cycles/sec}$$

[0197] Which gives a predicted radius of the electron as

$$r_e = 6.366\times10^{-19} \text{ m.}$$

[0198] So the half integer rotation velocity (revs.πr) is 2π/c !, for the electron in keeping with the harmonic balance of the electron.

[0199] The same principle may be used to obtain an accurate estimate of the spin and radius of the muon, or any other particle. Using the above formula

$$\text{revs} = hc^2/4m_e(2\pi)^4 \tag{31}$$

[0200] Then as the mass of the muon is 1.8823×10^{-28} kg then the revs of the muon $f_\mu = 5.070\times10^7$ cycles/sec and the radius (r_μ) is thus 1.316×10^{-16} m.

[0201] It is now possible to begin to explain how the muon and the other subatomic particles are formed. If a quasi electron is complexed with another structure the total geometric structure needs to maintain harmonic balance. So the frequency of rotation would need to match geometric sructure with which the quasi electron was complexed

[0202] Intriguingly we find asymptotic convergeance for the formulas for frequency and mass occurs, when the geometric structure complexed with the quasi electron has the structure represented by $(\pi/c^{1/3})$ [giving the frequency divided by two, because the single integer spin of the force carrying particles compares to a half integer spin for the muon]. So that

$$(f_\gamma 3\pi/2)^{1/3} = f_\mu$$

[0203] When the ratio of the masses of the electron (m_e) and muon (m_μ) are related, such that:

$$m_e(3\pi/c^{1/3}) = m_\mu$$

[0204] Indeed we find that (allowing for the neutrino) this ratio is very close to the actual ratio of the mass of the electron to the mass of the muon, determined experimentally.

[0205] Furthermore, we have seen that these geometric structures, representing harmonics of the speed of light, which either match the frequency or the amplitude of vibration of the quasi electron, mathematically define the masses of the particles and the fundamental forces of Nature.

Part III

Quantum Gravity

[0206] Quantum General Relativity

[0207] Given the overall energy "complex" energy tensor structure of the electron and the metric tensor, assumed in general relativity, the quantum nature of gravity itself can now be explored. The spherical complex tensor for the electron and the positron (eq. 4, 5, 6) give the mathematical quantum structure and energy tensor for all the other particles (see appendix 2). Together with the time dimension these nine space dimensions account for the 10 parameters present in the metric tensor necessary to formulate the equations for gravity using Riemann geometry and thus forms the basis of quantum gravity. Intriguingly the metric tensor at each point in space time is required to consist of a collection of ten numbers, Consequently, ten dimensional space-time hypotheses, such as this or superstring theory, do automatically yield general relativity.(ref 3)

[0208] Furthermore, the mathematical representation of the graviton and the gravitational constant may be directly estimated from the knowledge of the mass and radius of quintessence. Thence, the force of the vibrations of quintessence lead directly to quantum gravity.

[0209] The radius of quintessence should be approximately in keeping with the Planck length estimate (r), which is conventionally derived from the standard dimensional equation:

$$r_q^{\,2} \approx Gh/c^3 \tag{32}$$

[0210] Given the nine spacial parameters present in the metric tensor, used in general relativity we find that the actual formula for $r_q^{\,2}$ is mathematically in agreement with theory when:

$$9r_q^{\,2} = Gh/c^3 \tag{33}$$

[0211] This again supports the 9 dimensional view of space and the size of the vibrations of quintessence can thus be estimated.

$$r_q = 1.35\times10^{-35} m \tag{33a}$$

[0212] This value is in agreement with the Planck length. Indeed if the above equation is correct then we find that we can derive the standard equation for the general relativistic increase in radius, r', (eq. 34) directly from first principles and arrive at a more fundamental equation for quantum gravity. As

$$r' = G.M/3c^2 \tag{34}$$

[0213] By substituting eq 33) into equation 34, a fundamental relationship between r' and M is obtained.

$$r'/3r_q^{\,2} = GMc^3/Ghc^2 = Mc/h$$

[0214] And substituting the quintessential equation, $h=m^qc^2$ (eq. 1) then:

$$r'/3r_q^2=M/m_qc=n_q/c \tag{35}$$

[0215] Hence the ratio of the change in radius to that of the radius of quintessence squared, is proportional, by a factor of c, to the ratio of the mass M of an object to that of the mass of quintessence, effectively the number of quintessences. Thus the change in radius, r' due to gravitation, is related to none other than the ratio of the mass and radius of an object to the mass and the square of the radius of quintessence. Thus again the gravitational change in radius is directly related to the number of quintessences.

[0216] Naturally, this would be exactly what would be logically expected if quintessence, like the equation for the charge of the electron (eq. 6) forms from a root sphere. Thus the change in spacial radius of a normal sphere is dependant on the square of the quintessential radius.

[0217] This increase in apparent radius represents none other than the (gravitational) binding energy for quintessence.

[0218] The meaning of the above dimensional equation (33) might itself be further understood by substituting the mass of quintessence (where $m_q=h/c^2$) into the equation. Thus in nine dimensions the gravitational constant (G) may be more logically given as,

$$9(\pi r_q^2/m_q)=G\pi/c \tag{36}$$

[0219] Where πr_q^2 is the cross sectional area of quintessence and m_q is the effective mass of quintessence, and thus $(\pi r_q^2/m_q)$ represents the effective mass per unit area which quintessence exerts. This equation reduces to:

$$9r_q^2/m_q=G/c \tag{37}$$

[0220] From this we may derive the standard general relativistic relationship for the apparent change in radius (r') around a mass (M), from an understanding of the mass (m_q) and number (n_q) of qiuntessences. As $m_q=M/n_q$, then:

$$3r_q^2=G.M/3c.n_q \tag{38}$$

[0221] Then if

$$n_q=r'c/3r_q^2 \tag{39}$$

[0222] thus directly substituting for n_q in eq 38:

$$r'=G.M/3c^2 \tag{34}$$

[0223] The importance of this is that the gravitational change in radius now logically derives from equation 36, which describes the gravitational force as resulting directly from the mass of quintessence exerted/per unit area of quintessence.

$$9(\pi r_q^2/m_q)=G\pi/c \tag{36}$$

[0224] Thus equation 34 is the conventional equation for the general relativistic increase in radius (r') in a gravitational field, which is here derived from the underlying nature of quintessence. Thus the gravitational constant is derived from the mass and radius of vibration squared of quintessence from first principles.

[0225] Indeed it is apparent that a more fundamental equation for gravitation now exists, for equation (39) is mathematically accurate and numerically agrees with eq. 34:

$$r'/3r_q^2=n_q/c \tag{39}$$

[0226] These equations may be readily mathematically verified. If in accordance with standard general relativity, the apparent increase in radius r' is:

$$r'=GM/3c^2 \tag{34}$$

[0227] Then given that the mass of the Earth is 5.974×10^{24} kg;

$$r'=1.478\times10^{-3}\ \text{m}$$

[0228] Accordingly if $r'=3r_q^2n_q/c$; (eq.39). Given the number of quintessences (n_q) constituting the Earth is M_E/m_q, then

$$n_q=5.9745\times10^{24}/7.3725\times10^{-51}=8.104\times10^{74}$$

[0229] As $r_q^2=1.823\times10^{-70}$ (eq. 33a) then:

$$r'=1.478\times10^{-3}\ \text{m}$$

[0230] Thus equation 39 gives the same answer as the standard equation and may be understood on a logical basis. Indeed the meaning of c in the equation may be understood as it has been previously shown as being the basis for the radius of matter (eq. 6). Hence the general relativistic change in radius, r', is none other than the effective binding energy for quintessence.

[0231] Quantum Gravity and Wave Particle Duality

[0232] Quantum gravity can now be readily linked with quantum mechanics, indeed any observations which are self consistent must be able to do so easily.

[0233] The frequency of light has been previously derived

$$f=E/h=n_q$$

[0234] Thus the formula for the frequency of light (E=hf) has previously been explained theoretically by the simple observation that the frequency is determined quite directly from the number of quintessences (n_q) within the photon. The same principle has also been shown to apply to matter.

[0235] Let us now follow these equations for matter by calculating the wavelength of a photon from the Gravitational constant as an example; and also as a test of these observations and to demonstrate that the gravitational equations can also apply to the quantum world.

[0236] If

$$n_q=r'c/3r_q^2 \tag{39a}$$

[0237] where r' is the is the general relativistic increase in radius, and r_q is the radius of quintessence (eq. 33). Where $f=n_q$, substituting for n_q, then the frequency of the photon f_γ(where $\beta=1$) is given by:

$$f_\gamma=r'c/3r_q^2$$

[0238] Uing the standard equation, $r'=GM/3c^2$ (eq. 34); we may substitute for r', thus we have:

$$f_\gamma=GM/9r_q^2c$$

[0239]

Thus

$$f_\gamma=\frac{G}{9r_q^2c^3}\cdot m_\gamma c^2$$

and as $E=m_\gamma c^2$;

-continued

$$f_\gamma = \frac{GE}{9r_q^2c^3} \tag{40}$$

[0240] Indeed as $9r_q^2=Gh/c^3$, then

$$f_\gamma=E/h=n_q$$

[0241] It is possible to also demonstrate that the same relationship holds for the wave equation for matter. If we take the relativistic wave energy of matter, which has been previously derived,

$$f=\beta^2 n_q$$

[0242] This includes the term for the number of quintessences flowing through the electron, in the complex vectors of space-time, to give the relativistic electron momentum (ρ) and a term for the rest mass, thus substituting into (40)

$$f_\gamma = \frac{GE}{9r_q^2c^3} \tag{40}$$

[0243] As $f=\beta^2 n_q$ for matter then the equation expands to:

$$f_m = \frac{G}{9r_q^2c^3}\cdot\beta^2E$$

As $\lambda = v/f$, then

$$\lambda = \frac{9r_q^2c^3v}{G\beta^2E} \tag{41}$$

[0244] Then the equation again reduces to:

$$G = \frac{9r_q^2c^4}{\lambda\beta E} \tag{3}$$

[0245] Equations 3, 40 and 41 are important as they show that the quantum wavelength of any particle of rest mass m can be derived from the gravitational constant G. Thus linking quantum mechanics to quantum gravity.

[0246] It is therefore important to confirm the numerical accuracy of the above equation (40). We can do this by comparing the result to the standard computation of the de Broglie equation, in a range where de Broglie itself is likely to be most accurate; which according to these observations is in the low energy range (see section on Wave Particle Duality).

[0247] If we take an electron with an energy of 0.1 KeV the wavelength is conventionally given (where the kinetic energy of the electron E_K is given by the product of the charge of the electron (C) and the potential applied eV=0.1 Kev), by the standard equation:

$$\lambda=h/p=h/(E_K.2m_0)^{1/2}$$

[0248] thus

$$\lambda=6.63\times10^{-34}/[1.602\times10^{-19}\times1\times10^{2}\times18.22\times10^{-31}]^{1/2}$$

[0249] hence

$$\lambda\cong1.23\times10^{-10}\,m$$

[0250] Using

$$\lambda = \frac{9r_q^2c^4}{G\beta E} \tag{3a}$$

[0251] Where $E=\gamma m_0c^2$

[0252] At 0.1 Kev, electron velocity is 6×10^6 r/sec, thus $\beta=2\times10^{-2}$ and $\gamma=1/(1-v^2/c^2)^{1/2}=1.0002$ Thus:

$$\lambda = \frac{9\times1.82\times10^{-70}\times80.78\times10^{32}}{6.67\times10^{-11}\times\beta\times1.0002\times9.11\times10^{-31}\times8.998\times10^{16}}$$

$$\lambda = \underline{1.21\times10^{-10}m}$$

[0253] Divergence between the de Broglie equation and the above equation (2) occurs at intermediate and high energies where it is generally accepted that the standard de Broglie equation may be less accurate (ref 18). The values for eq. 2 and de Broglie are compared to recent experiments, which demonstrate a relativistic curvilinear plot for wavelengths of matter in keeping with eq. 40.(ref 1)

[0254] The de Broglie equation in the non-relativistic format yields a simple log/linear scale, which is not in keeping with relativity; whereas eq. 3 is dependent on relativity and mathematically accounts for both relativity in calculating the wavelength. Indeed recent experiment on quantum tunnelling through a wire mesh strongly suggests that the relationship between energy and wavelength is relativisticalty curvilinear.(ref 1) Furthermore equation 3a suggests a fundamental relationship between energy (E), relative velocity (v/c =β), gravity (G) and the quantum wavelength (λ)

$$\lambda = \frac{9r_q^2c^4}{G\beta E} \tag{3a}$$

[0255] Indeed as ${}^9r_q^2$ =Gh/c^3, then

$$\lambda=hc/\beta E \tag{2}$$

[0256] Equation 2 is the very same as the Universal wave equation derived form first principles for the wavelength of tight and matter, which allowed a relativistic solution to the equations for wave particle duality (see Wave Particle Duality). This now indicates that these quintessential equations are compatible with relativity, quantum mechanics and quantum gravity.

[0257] Graviton Structure

[0258] From these observations, if the value for the gravitational constant is substituted into the equation (35) we may now estimate the probable geomteric structure of the gravtion, which is the force particle mediating gravity by acting on quintessence. Thus the Gravitational constant has been previously derived from the vibration of quintessence by the equation:

$$G.(\pi/c)=9(\pi r_q^2/m_q) \tag{36}$$

[0259] This is in accurate agreement with the value for G (6.67×10^{-11} N m^2 kg^{-2}). This suggests that the most probable mathematical representation of the graviton (ϕ), the third force carrying particle is

$$\phi=(\pi/c). \tag{42}$$

[0260] Thus the gravitational constant (G) can be given by the mass and radius of quintessence and the structure of the graviton

$$G=9\pi r_q^{\,2}/\phi.m_q \tag{43}$$

[0261] This shows the gravitational force to be related to the fundamental radius of quintessence space time, and the graviton.

[0262] Quantised General Relativity

[0263] The classical general relativistic formula, as given by Einstein is:

$$R_{\mu\nu}-\tfrac{1}{2}g_{\mu\nu}R=-\kappa T_{\mu\nu}$$

[0264] Where R is effectively the curvature of space-time, $R_{\mu\nu}$ denotes the contracted Riemann tensor of curvature and $T_{\mu\nu}$ is the "energy tensor" of matter.(ref 3)

[0265] If we substitute the energy tensor matrix of the electron (eq. 9) x time, for the energy tensor of matter $T_{\mu\nu}$; and the metric tensor of the space-time lattice x time for the contracted Riemann tensor we can arrive at the same solutions for general relativity.

[0266] Furthermore, in his published paper on General Relativity, Einstein(ref 3) defined the constant κ as:

$$\kappa=8\pi G/c^2$$

[0267] Therefore Einstein's equation should be written as

$$R_{\mu\nu}-1/2g_{\mu\nu}R=-\frac{8\pi G}{c^2}\cdot T_{\mu\nu} \tag{43}$$

[0268] Einstein himself was apparently not happy about the right hand component of the equation. However, we find that this part of the equation can now be explained and quantised by substituting the gravitational constant, $G=9\pi r_q^{\,2}/\phi.m_q$, (eq. 42a),

[0269] Giving:

$$R_{\mu\nu}-1/2g_{\mu\nu}R=-\frac{8\pi^2\cdot 9r_q^2}{\varphi\cdot m_q\cdot c^2}\cdot T_{\mu\nu} \tag{44}$$

[0270] By substituting $m_q.c^2=h$, and further substituting $h=h/2\pi$, we arrive at a quantised solution to Einstein's equations. Where A_q is the surface area of quintessence ($A_q=4\pi r_q^{\,2}$); ϕ is the graviton [ϕ=(π/c)] and h is Plancks constant. thus:

$$R_{\mu\nu}-1/2g_{\mu\nu}R=-\frac{9A_q}{\varphi\cdot\hbar}\cdot T_{\mu\nu} \tag{45}$$

[0271] The gravitational equation can now be further understood on a logical basis. The term $A_q=(4\pi r_q^{\,2})$, where $(4\pi r_q^{\,2})$ represents standard term for the surface area of a sphere of quintessence for the 9 space dimensions of the space time lattice, h is the energy content of quintessence x time and ϕ is the graviton, thus the right hand term now represents a true "metric energy tensor" of matter.

[0272] This leads directly to the standard solution to the field equations, for the general relativistic increase in radius r' of an object, where A is the surface area of a sphere of a given mass M, such that

$$r'=\surd(A/4\pi)-r=GM/3c^2 \tag{34}$$

[0273] Furthermore, although equation 45, gives the same solutions as Einstein's equation, which is essentially correct, the difference is that the equation is now dependant upon Planck's constant (h), and moreover the radius of quintessence, which now defines a quantised solution to the equations.

[0274] Graviton Force Characteristics

[0275] Similar to the photon, the previously derived equation (42) for the graviton [(ϕ=(π/c)] appears to also mathematically represent a helical ringlet of quintessence, but with a spin of 2. For the photon, taking the direction of motion as the x vector and its axis of spin also as the x vector, would account for the electromagnetic force and its attraction and repulsion characteristics. In the case of the gluon component ($\pi/c^{1/2}$), if the direction vector is x, then the axis of spin would be in the y vector, the same as quasi electrons, accounting for the particle binding characteristics of the gluon force. (see; Gluon structure and force characteristics. Appendix 2). In the case of the graviton, if the direction of motion was in the x vector, the graviton spin axis would be in the z vector thus, as will be demonstrated, accounting for the gravitational force.

[0276] The spin axis of the graviton can also be derived using the known characteristics of the electron. If an electron is travelling in the x direction, then its spin axis is determined by the by the sign of the ${}_{j}y$ vector (up or down). This view is in agreement with conventional theory, which indicates that the electron spin is similar to a rotating planet orbiting the sun, (the electron even appears to have orbital precession). As the electron passes through the space-time lattice, this spin would generate the formation of gravitons. This would occur as a result of the ejection of the excess quintessence passing through the electron. As the electron spins, the ejection of these gravitons would occur at a tangent to the electron's direction of motion. The ejection of the gravitons would occur, similarly to the ejection of energy of a pulsar or quasar, through the equivalent of the north and south poles of the electron. Thus, propelling the graviton in the direction of the electrons y vector. The ejection of the graviton would re-orientate and impart a specific angular momentum to the gravitons which would thus end up spinning on its own z axis. If for instance the graviton is released from an up spin electron the graviton will be rotating clockwise and its leading edge will displace quintessence downwards. In turn this will provide an upwards force.

[0277] This picture accounts for Fleming's left hand rule, is logical and provides an explanation for the magnetic force around a wire. According, to the left hand rule if the direction of the current is in the x vector, the magnetic field is in the z vector, and the force is upwards, in the y vector, in accordance with the above model. Therefore, this particular spin axis and the structure of the graviton results in its force characteristics. As the graviton is very small compared to the electron and both have different rather rapid spin axis it is difficult for these to bind and interact. Nevertheless, because the graviton has a spin of 2, and as it spin axis is perpendicular to its direction of motion, in the z vector, it readily displaces space-time quintessence to produce gravity. Thus because the graviton is able to displace space-time, it is capable of escaping a black hole. How else could the effects of gravity be felt beyond a black hole?

[0278] Quantum Gravity and Electromagnetism

[0279] With the above electron model of graviton production (see pp. 32), the nature of magnetism can be understood from first principles, Furthermore, the presence of a space-time lattice links relativity, and the forces of gravity with the electromagnetic and other forces of Nature. Indeed, evidence for these links may first date back to the 1820's, when Andre Ampere first defined the Amp. The force of attraction between two parallel wires 1 metre apart each carrying 1 Amp in a vacuum was defined as none other than the permeability of free space (2×10^{-7} N per metre of conductor). Thus conventionally the magnetic field strength around a long straight wire is given as:

$$B=\mu_0 I/2\pi r$$

[0280] Where I is the current and μ_0 is the permeability of free space ($4\pi\times10^{-7}$ N A^{-2}).

[0281] The attraction between two wires both carrying negative charge is, however, counterintuitive as negative charges should repel. A conventional explanation overcomes this by invoking the presence of a magnetic field which is created by the current by the production of virtual photons. Thus we appear to have an explanation for the effects of magnetism which involves virtual photons, however, these photons are not observed. More accurately, according to conventional special relativity the magnetic field is none other than the electric field viewed relativistically(ref 19).

[0282] A more satisfactory explanation, therefore, lies in the interaction between the electrons and the space time lattice. The moving electrons in the two wires interact with the lattice to produce gravitons; which are in phase when both streams of electrons are travelling in the same direction. The gravitonic waves interact constructively to disperse the space time lattice between the wires and induce an attractive force between the two wires, which produces in effect the permeability of free space. Thus this force results from the vibration of quintessence itself.

[0283] Conversly in two wires with current going in opposite directions the graviton waves are in anti-phase and would interact destructively between the wires. The gravitonic waves travelling radially outward from the wires would, however, disperse the lattice outside the two wires and produce apparent repulsion between the wires, which is exactly what is observed. These effects of electricity suggest that gravitons act as waves and that phase is important.

[0284] This effect is also seen with the north and south poles of ferromagnets. Nevertheless, with matter other than iron, cobalt or nickel, the graviton emission cannot be phased as the atoms are unable to align and magnets do not appear to exist with other materials.

[0285] In ordinary magnetic system the release of gravitons from the north pole would be exactly balanced by those released from the south pole of the magnet and hence there would be no nett force on the magnet until an external magnet or electrical current were applied.

[0286] Overall the magnitude of the forces in electrical systems where electrical conduction occurs are well defined by the permeability and permittivity of free space μ_0, and ϵ_0. Where v is the constant velocity of the charge and ϵ is the electric field produced by the charge.

$$B=[\mu_o.\epsilon_0]v.\epsilon$$

[0287] These observations suggest that the forces of electricity which produce magnetism are indeed related to the permittivity and permeability of free space and that these quantities are exerted by an apparent vacuum. Thus the effects of magnetism could be explained by none other than the phased effects of gravitational waves on the space time lattice.

[0288] Electromagnetism is of further interest to quantum gravity, particularly if we combine the standard equations, $B=\mu_0 I/2\pi r$ and $B=[\mu_o.\epsilon_0]v.\epsilon$, substituting for B we have:

$$2\pi r=I/\epsilon_0.v.\epsilon \tag{46}$$

[0289] Thus $2\pi r$ is proportional to the inverse of ϵ_0. Thus as space time is dispersed by gravitons the permittivity field will increase in the same way capacitance increases with separation of plates. Because of the inverse relationship between ϵ_0 and $2\pi r$, as ϵ_0 increases the circumference of a circle and the apparent ratio of π is to r, will appear to diminish in accordance with general relativity. This not an actual diminution in the circumference of a circle but the effective reduction of the resistance to motion in a circular path in this field.

[0290] Incidentally, the above observations, also lead us directly to Shrödinger's formula for the average equilibrium distance (r) between an electron with charge (e) in orbit around a proton, which is conventionally given by:

$$r=n^2 4\pi\hbar^2\epsilon_0/me^2$$

[0291] Where ϵ_o is again the permittivity of free space, m is the mass of the electron and n is an orbital integer, h is Planck's constant and e is the charge of the electron. Furthermore if $e=[\epsilon_0/3(4/3\pi c^3)]^{1/2}$ (eq.3); then the equation at n=1, for the electron orbital radius elegantly simplifies to:

$$r=4h^2c^3/m$$

[0292] Hence the orbital radius of the electron is related to spin of the electron (h) and its mass (m).

[0293] Quantum Gravity and the Charge of the Electron

[0294] The equation for the charge of the electron (eq. 1) contains the term so (permittivity of free space) which according to these observations should vary in a gravitational field.

$$e=\left[\frac{\varepsilon o}{3(4/3\pi c^3)}\right]^{1/2} \tag{6a}$$

[0295] If we combine the standard equations, $B=[\mu_0 I/2\pi r$ and $B=(\mu_o.\epsilon_0]v.\epsilon$, substituting for B we have:

$$2\pi r=I/\epsilon_0.v.\epsilon \tag{46}$$

[0296] Thus $2\pi r$ is proportional to the inverse of ϵ_0. Thus as space time is dispersed by gravitons the permittivity field will increase in the same way capacitance increases with separation of plates. Because of the inverse relationship between ϵ_0 and $2\pi r$, as ϵ_0 increases the circumferance of a circle and the apparent ratio of π to r, will appear to diminish in accordance with general relativity.

[0297] Thus ϵ_0 rises when space-time is dispersed by the gravitons that produce the gravitational field, This occurs in a similar way to the process by which capacitance increases with separation of plates in a capacitor.

[0298] Nevertheless, as c is a constant and as $c=[\mu_0.\epsilon_0]^{-1/2}$, then if ϵ_o rises then μ_0 falls. This is entirely consistent as μ_0, which represents the force that quintessence exerts, would be reduced if the quintessence space time lattice is dispersed.

[0299] Furthermore, as $\mu_0=4\pi \times 10^{-7}$ N A^{-2}; then as μ_0 falls, then the appareent ration π to r, also falls in a gravitational field. This is largely the same as stating, as does general relativity, that the apparent radius r', rises in a gravitational field. So this view is consistent with general relativity.

[0300] Nevertheless, to derive an exact value for the charge of the electron we must account for gravity in the above equation. We will take the specific example of the Earth's gravitational field in order to obtain the exact value for the electron. If in accordance with standard general relativity, the apparent increase in radius r' is:

$$r'=GM/3c^2 \tag{34}$$

[0301] Then given that the mass of the Earth is 5.9745×10^{24} kg; then

$$r'=1.47864\times 10^{-3}\ m$$

[0302] thus

$$2\pi r'=9.29057\times 10^{-3}$$

[0303] Which is the incremental factor by which ϵ_0 must increase in Earth's gravitational field. So to correct ϵ_0 to account for gravity, ϵ_0 must be divided by the incremental factor, 2πr'. Similarly as effectively π decreases in a gravitational field, to correct π to account for gravity it must be multiplied by this incrememtal factor. So the equation for an electron in a zero gravtational field is:

$$e=\left(\left[\frac{\varepsilon o}{3(4/3\pi c^3)}\right]\right)^{1/2}\div(1+2\pi r')=1.6022\times 10^{-19}\ C \tag{6b}$$

[0304] This now gives the charge of the electron as measured in a zero gravitational field as 1.6022×10^{-19} C, which is the same as that measured on Earth. Notably these observations appear to suggest that the charge of the electron is the same irrespective of the gravitiational field.

[0305] Virtually unlimited degrees of accuracy for the charge of the electron and for the fine structure constant (α), may be achieved by taking into account 2nd and nth order gravitometric effects. Thus if we take into account the effect of gravity upon the radius of the Earth it is also important to take into account an effect a upon the instruments with which we measure quantities, this would be a second order gravitometric effect. Thus taking into account 2nd order effects (r"), we have a very small, but nevertheless relevant change, such that: r"=r'(1+2r'). Thus $2r''=9.3180486\times 10^{-3}$, and thus:

$$e=\left(\left[\frac{\varepsilon o}{3(4/3\pi c^3)}\right]\right)^{1/2}\div(1+2\pi r'')=1.6021765\times 10^{-19}\ C \tag{6c}$$

[0306] This agrees exactly to the nearest 7 decimal places with the maximum accuracy of the experimental value for the charge of the electron.(ref 15) Furthermore by taking into account the nth order gravitometric effect, it is theoretically possible to predict accuracy for the charge of the electron to 3n decimal places. This mathematically accuracy confirms the structure of the electron from first principles and indeed the theoretical effects of gravity on the permittivity of free space (ϵ_0).

[0307] This returns us directly to the fine structure constant for the electron which is conventionally given by: $\alpha=e^2/\hbar c.4\pi\epsilon_0$. If $e^2=\epsilon_0/3(\tfrac{4}{3}\pi c^3)$, accordingly the quintessential equation for α is structurally given by: $2\pi/\alpha=m_q[3\Theta]^2$ (where $\Theta=\tfrac{4}{3}\pi c^3$; see The Structure of the Electron and Matter), we must now take into account the effects of gravity, as above, thus:

$$\alpha 2\pi/m_q[3\Theta]^2\div(1+2\pi r'')^2=0.007297353$$

[0308] Where the gravitational term for the increase in radius r" allows the mathematical derivation of α, and the above equation is in agreement with the conventional experimental value for α=0.007297353 to the nearest 9 decimal places.(ref 15)

[0309] Hence the term $(1+2\pi r'')^2$ is in accordance with these observations for the effect of gravity on electromagnetic forces. To a maximum accuracy governed by current knowledge of the mass of the Earth and the Gravitational constant and thus the term for the gravitational increase in radius r'. These observations can also be used to accurately predict the magnetic moment of the electron (see Quantum Gravity and the Electron Magnetic Moment).

[0310] Thus the presence of the fine structure constant can now be further understood, by deriving the constant from first principles; specifically from the actual dimensional conformation for the charge of the electron: $e=[\epsilon^0/3(\tfrac{4}{3}\pi c^3)]^{1/2}$ (eq. 6).

[0311] Overall the fine structure constant α (allowing for the term r' which is the general relativistic increase in the radius of the Earth due to gravitation) is given by none other than the formula for the mass of quintessence and from the structure of the electron, which can now be derived from first principles to seven decimal places or more.

[0312] Quantum Gravity and the Electron Magnetic Moment

[0313] The theoretical origin and nature of magnetism remains obscure in current electromagnetic theory. An explanation suggests these magnetic effects are produced by photons, although no photons have ever been observed. To get round this difficulty it is postulated by physics that magnetism results from "virtual" photons. However, Maxwell's equation for electromagnetism states that the photon has no nett magnetic effect.

$$\delta B_x/\delta x+\delta B_y/\delta y+\delta B_z/\delta z=0$$

[0314] Thus magnetism could not, by the above standard equation, be derived from a photon real or virtual.

[0315] In addition observational data suggests that black holes have powerful magnetic fields and as in theory photons are unable to escape from black holes (except for small quantites in the form of Hawking radiation), it would be difficult to explain these magnetic fields on the basis of photon emission.

[0316] Einstein postulated that magnetism was merely due to special relativity (ref 17). The postulate for the nature of magnetism in these current observations, states that the magnetic force results from relativity due to none other than the phased emission of gravitons (why postulate two invisible forces, magnetism and gravity, when one, the graviton, will do). This view as previously discussed (Quantum Gravity and Electromagnetism) is entirely compatible with standard relativity.(ref 19) Thus with the graviton origin of magnetism, the equation for the magnetic moment of the electron should have an expression in terms of quintessence and in turn the gravitational force and in particular the graviton.

[0317] The standard term for the magnetic moment of the Bohr Magneton (SIB) is:

$$\mu B=eh/4\pi m_e$$

[0318] In standard quantum mechanics the Bohr Magneton, μB, however, needs to be corrected to agree with experiment. The "correction factor" is termed "ϵ"; where $\epsilon=(\alpha/2\pi)-0.328\alpha^2/\pi^2)=0.001159641$. Thus theory reveals μ_e, the magnetic moment of the electron where:

$$\mu_e=(eh/4\pi m_e)[1+(\alpha/2\pi)-0.328\alpha^2/\pi^2)]$$

[0319] The conventional derivation of the term ϵ above, is given from the fine structure constant, $(\alpha/2\pi)$ which is theoretically consistent. However, a rather arbitary mathematical correction term; $0.328\alpha^2/\pi^2$ needs to be used in this standard equation. This appears ad hoc and needless to say, more accurate measurements show , the electron magnetic moment to the Bohr magneton ratio, $1+\epsilon=1.001159652$, which suggests the correction factor is indeed incorrect. Nevertheless, this correction factor is essential for "renormalisation" and thus for quantum mechanics to work.

[0320] Quantum gravity readily explains the discrepancy between the theoretical Bohr Magneton (μB) and the actual measured magnetic moment of the electron (μ_e). In accordance with the above chapter (Quantum Gravity and the Charge of the Electron)

[0321] Thus the significant mathematical discrepancies can be removed by accounting for the effects of quantum gravity.

[0322] Thus taking the charge of the electron (e), using the equation for the Bohr magneton and the effects of quantum gravity such that gravitational change in radius is r". The magnetic moment of the electron is given by:

$$\mu_e=(eh/4\pi m_e)(1+[\alpha/2\pi\div(1+r'')])$$

[0323] This gives an electron magnetic moment to Bohr magneton ratio of 1.00115968. Thus the mathematical term for the magnetic moment of the electron is given, avoiding the arbitary and dubious term $0.328\alpha^2/\pi^2$ used in the standard equation, simply by accounting for quantum gravity.

[0324] It is now possible to unite the equations for gravity and magnetism by substituting the fundamental key equations of quantum gravity. Thus if: $h=3m_qc^2$ (eq 1b) and $m_e=m_q.n_q$ (eq. 2). Then we can express the magnetic moment of any particle with the charge of the electron, including the proton, in terms of the number of quintessences (n_q) in that particle.

$$\mu B=ec^2/{}^4\!/_3\pi n_q \tag{47}$$

[0325] Given that the postulated structure of the graviton is: ($\phi=\pi/c$ (eq. 42), then substituting we have

$$\mu B=3ec/4\phi n_q \tag{48}$$

[0326] Showing that the equations for the magnetic moment are compatible with the gravitational equations given earlier. Principally, the quintessential equations now allow the determination of the magnetic moment of any charged object from the equation for the graviton and directly from the number of quintessences it contains. In conventional physics the magnetic moment of the electron requires a correction factor, $(1+(\alpha/2\pi c)-0.328\alpha^2/\pi^2))$, to derive the correct experimental value. These observations herein, indicate that the correction factor is more logically (1+r"), where r" is the general relativistic increase in radius around a gravitational body. This suggests that magnetism is not only affected by gravity, but can, as shown as above, be derived using the quantum gravitational equations.

[0327] Quantum Gravity and Special Relativity

[0328] Ordinary matter passing through the lattice would produce gravitons which would interact with space-time as described by general relativity. The quantity of gravitons would be determined by the apparent mass and in turn these would apparently curve space time. The geometry of this "curvature" is elegantly described by general relativity using Riemann geometry, specifically using metric tensors. Intriguingly the metric tensor is not a single number, but at each point in space time it is required to consist of a collection of ten numbers, Consequently, ten dimensional space-time hypotheses, such as this or superstring theory, may automatically yield general relativity. (see quantum general relativity p. 36)

[0329] General relativity is indeed very elegant, nevertheless there was a logical step yet to answer. That is, how do gravitons shape space time? This can now be readily answerd by considering the interaction of a three dimensional space time lattice with gravitons themselves to produce the effects of gravity. The effects of gravity are as such to compel a body in motion towards the gravitational object and to a much smaller extent visa versa. This effect can only be produced If gravitons repel quintessence (the constituents of the 3D lattice). Indeed, it has been stated that in order to explain cosmic inflation and the "flatness" of the Universe that quintessence must shun (or be shunned by) matter (ref 5,6,7).

[0330] In descriptive terms a body close to a large mass will have a tendency to move toward it because the three dimensional lattice would be less dense as it approached the surface of the large mass. Overall there would be less resistance to motion in the direction of the large mass, and the motion in this direction would be facilitated by the vibration of quintessence.

[0331] In general relativity the principle governing motion is the geodesic of least distance, this can be re-expressed using similar equations using least action. Furthermore, the concept of motion due to the vibrations of quintessence is more logically and experimentally compelling.

[0332] These observations can now be used to link general and special relativity. Thus as we approach the speed of light, the mass of an object travelling through the space-time lattice would approach infinity, directly because the number of quintessences passing through a body would increase with increasing velocity, hence the equation:

$$m'=m_0/(1-v^2/c^2)^{1/2} \quad (50)$$

[0333] or

$$m'=m_0/(1-v^2[\mu_0.\epsilon_0])^{1/2} \quad (50a)$$

[0334] In turn this would generate increasing gravitons and accordingly this would explain the observed effects of special relativity. Time itself is due to passage through the space-time lattice, and where the space-time lattice is dispersed by gravitons, time and length are reduced with increasing velocity and hence increasing space-time lattice dispersion, similar to the way in which gravity alters space-time

[0335] As a result:

$$t'=t(1-v^2/c^2)^{1/2},\ l'=l(1-v^2/c^2)^{1/2}$$

[0336] Thus resulting in the effects of special relativity.

[0337] Quintessence and Black Holes

[0338] To address the relationship of the space-time lattice to gravity directly, it is important to discuss the concept of quintessence with regard to general relativitivistic equations. The standard general relativistic equation for the apparent increase in radius (r) due to the curvature of space time around a gravitational object, which has also been previously derived from first principles (eq. 36), is:

$$r'=G.M/3c^2 \quad (34)$$

[0339] This can also thus be written as:

$$3r'=G.M[\mu_0.\epsilon_0] \quad (51)$$

[0340] This standard equation, is in keeping with the above observations. Specifically, as the mass increases, ϵ_0 increases, in turn the radius will appear to increase (relative to π).

[0341] The above observations now allow us to examine the effects with regard to the interior of black holes themselves. The event horizon would represent a critical density for quintessence, in which light could not escape. The Schwarzschild radius would now be given by:

$$R_s=2GM[\mu_0.\epsilon_0]$$

[0342] The event horizon will occur at the point at which there is less resistance to circular motion than motion in a straight or partially curved line. Given that π is proportional to $1/\epsilon_0$. The event horizon should occur when the permittivity has increased by a factor of π.

[0343] Effectively because the permittivity of free space rises, π decreases. This is entirely in keeping with general relativity which predicts the effective change in the ratio of the radius to the circumference as given by the conventional equation, where r', is again the apparent change in radius.

$$r=G.M/3c^2$$

[0344] Hence π will effectively decrease as we approach the event horizon of a black hole, When π decreases to 1, the circular circumference is equal to the diameter and moreover, inside this limit it is shorter for light to travel in a circle. Thus light cannot escape the event horizon.

[0345] This can give us great insights into the workings of space-time, for flat Euclidean space the standard equation is:

$$e^{i\pi}=-1$$

[0346] In accordance with general relativity, the ratio of the radius to the circumference changes in a gravitational field, and effectively π=1, at the event horizon, thus the boundary condition for the shape of space-time at the event horizon now has the direct equation:

$$e^{f}$$

[0347] Within a black hole as the permittivity of space increases by a factor of 2π an object within it will complete two rotations rather than travel in a straight line. In effect exceeding the speed of light by 2π. Hence, the condition for space-time is represented by the equation:

$$e^{i/2}$$

[0348] Thus an increase in the permittivity of free space by a minimum factor of π, to produce a black hole is estimated to result from an increase in mass by a factor of approx. 10^6 (the ratio of the mass of the earth and that of a putative black hole).

[0349] Continuing with the subject of a black hole, according to the model inside the black hole, the gravitons produced by the matter present would be in equilibrium with the density of the space-time lattice. Increasing the rate of rotation of the matter in the black hole for instance would thus increase the production of gravitons and its effective mass and increase the radius of the event horizon. A density gradient of the space-time lattice would continue to exist within the black hole. Progressively closer to the centre of a black hole matter itself would be increasingly compressed and the spherical structure of the quasi electron would be predicted to collapse. This collapse would result in the formation of an exotic form of matter in the form of pure quintessence in a black hole.

[0350] This pure quintessence would produce the singularity at the centre of the black hole. The larger the black hole in terms of mass the more pure quintessence would exist at its core.

[0351] Quintessence and the Big Bang

[0352] Quintessence theory not only predicts the occurrence of the Big Bang, but allows a prediction for the value of the entire mass of the Universe, from first principles.

[0353] In accordance with quintessence theory the big bang resulted from the explosion of an immense black hole singularity, which was constituted from pure quintessence.

[0354] On the basis of quintessence, there will be a critical mass for Big Bang event; thus if entire space-time between quintessence is compacted so that no further quintessence can be accommodated, the addition of further quintessence would destabilise the immense black hole, resulting in the Big Bang.

[0355] It is possible to predict this critical mass, using the radius of quintessence as a benchmark. Given the nine spatial parameters present in the metric tensor, used in general relativity we find that the actual formula for the radius of quintessence; r^{q2}, is mathematically in agreement with general relativistic theory when:

$$9r_q^2=Gh/C^3 \tag{33}$$

[0356] This again supports the 9 dimensional view of space (so crucial in superstring theory). Moreover, the size of the vibrations of quintessence can thus be calculated as:

$$r_q=1.35\times10^{-35}m \tag{33a}$$

[0357] The volume of each quintessence is thus:

$$\tfrac{4}{3}\pi r_q^3=1.0306\times10^{-104}\,m^3 \tag{33b}$$

[0358] So to be accommodated within unit volume of space time, with no intervening apparent space time, (given that each of 9 overlapping quintessences are required) would require approx.

9×10^{104} quintessences

[0359] As the mass of quintessence is $m^q=h/c^2=7.373\times10^{-51}$ kg.sec (eq. 1). Then the mass of of the Universe, to two decimal places, is:

$$1.18\times10^{53}\text{ kg} \tag{33c}$$

[0360] This is in close agreement with a recent estimate of the mass of the Universe from COBE and other satellite data, which estimates the mass to be 100 trillion trillion trillion trillion tonnes (10^{53} kg). (ref 20)

[0361] Moreover, the early formation of the galaxies can be readily explained, it is likely that in such a big bang some very small black holes might have prevailed and that these formed the seeds of the galaxies we see today.

[0362] The event horizon, calculated from the Schwartzschild radius, of such an immense black hole is $\sim10^{26}$ m, which would have allowed Guth's inflationary component to the early expansion of the Universe.

[0363] In addition, inflation may result directly from the observation that once electrons have formed from the primordial soup of quintessence, they emit gravitons which in turn repel space time, which might also result in another cosmic inflationary cycle.

[0364] Most importantly quintessence theory explains the Big Bang from first principles and and is capable of accurately predicting the mass of the Universe.

[0365] The Nature of Energy

[0366] Foremostly, these observations allow a fundamental understanding of energy. The quantum physical, minimum component of energy is Planck's constant; h. To define the minimal component of mass, using the standard energy equivalence formula; $E=mc^2$, such a minimal mass (m_q) would be required to have the value equivalent to; $m_q=h/c^2$ (1). The total mass of a system (m) would then be; $m=m_q n_q$, where n_q is the number of these minimal units. Thence, the total energy of a system can be derived from the minimal energy; h, multiplied by the number of these energy units (n_q). Thus as, $E=mc^2$, then also $E=m_q n_q c^2$ and substituting $m_q=h/c^2$, the energy equivalence formula has the more logical formulation;

$$E=hn_q \tag{1a}$$

[0367] Thus the energy of a system is equivalent to the minimal energy unit; h, multiplied by the number of those minimal energy units (n_q).

[0368] This leads directly to a deeper understanding of wave particle duality and the wave nature of matter.

[0369] This is encapsulated by the quintessential energy formulae

[0370] As conventionally $\beta E/c=p$, then

$$\lambda=h/p=hc/\beta E \tag{2}$$

[0371] and

$$E=hn_q \tag{1a}$$

[0372] then

$$\lambda=c/\beta n_q \tag{2b}$$

[0373] Importantly, as indicated by equation (2b), energy having no quintessence; would have a wavelength of infinity. Specifically pure energy containing no quintessences, would have a lambda of infinity. According to quantum mechanics an infinite wavelength would result in the probability of that energy being anywhere. As energy itself has no electrical charge it would not be impeded by the permittivity and permeability of the three dimensional space-time lattice. Moreover, energy would not be detectable in three dimensional space-time, unless it interacted with matter, as in the EPR experiments. Indeed, energy is not observed when not bound to any form of mass or particle.

[0374] Thus equation 2b, takes us to our original assertion regarding the existence of pure energy.

-Energy is not bound by the space-time lattice-

[0375] Thus, as the EPR experiments suggest the existence of energy separate from matter and thus separate from the three dimensional space-time lattice, it is interesting to find that experiment suggests the existence of free energy in a continuum separate from space time and matter to produce the effects of quantum teleportation.(refs 10, 11, 12, 13)

[0376] This is not, however, teleportation across an additional dimension, this is a term to describe in partially familiar terms the dissociation of energy from the three dimensional space-time lattice. As time is inextricably linked to each dimension of space, the effects of energy would be inextricably linked to the events, such as the creation of virtual particles, we see interacting within space-time. It is unlikely that observers have any direct day to day experience to explain quantum events. Nevertheless, quintessence theory may have given us a window into the hitherto hidden workings of the Universe. Thereby, the mystery of the uniformity of the Universe, across distances which the speed of light could not apparently traverse, is readily explained by the fact that the free energy contained in the Universe is not bound by the space-time lattice.

[0377] In the case of light, due to the exceedingly small masses involved, there would be relatively easy exchange of matter with free energy within a photon. This would make the photon the ideal experimental tool to look for energy which is not bound by matter and in turn energy which is not bound in space-time. Indeed, very recently Furusawa et al. have reported to have observed the transference of energy as photons from A to B, without those photons traversing space-time(ref 10). This finding which has been supported using other experimental techniques(refs 11, 12, 13,), is very important as it suggests the existence of such free energy.

[0378] Overall, quintessence theory gives an a priori explanation for the concept of mass, the elementary particles, the forces of nature and quantum effects. It can equally be used logically to explain the inner physics of a black hole, the missing mass in the Galaxy, the expansion of the Universe, Guth's inflationary theory and predicts the Big Bang, from first principles.

Prior Art

[0379] Antigravity Systems

[0380] Recent research at NASA indicates that an antigravity device may be feasible. This research, however, has been undertaken at NASA without fundamental knowledge of the theoretical basis of quantum gravity. In these experiments the use of radio frequency (RF) pulses, such as in Nuclear Magnetic resonance, on rotating superconducting discs has been attempted, to produce antigravity effects.(ref 21)

[0381] However, radio frequency pulses are a weak form of electromagnetic radiation and are therefore unlikely to provide sufficient energy to produce measurable antigravity effects.

[0382] The warp drive technology described in this application is entirely different to previous prior art. The most important difference relates to the nature of the invention. In this application specifications are given for a direct drive system, as opposed to a gravity shield device, which other inventions claim. There is of course a vast difference as a shield device, merely reduces the force of gravity, but does not directly produce drive.

[0383] The references specifically relating to the shield effect are:

[0384] Other devices produce an attractive effect, as in an electromagnet magnet, which is again entirely different to the direct production of drive.

[0385] HOOPER U.S. Pat. No. 3,610,971 Apr. 15, 1969

[0386] In these and other antigravity devices the use of equal and opposite currents in a superconductor to produce anti-gravity effects are disclosed, as in:

[0387] BETTELS DE19832001 Jul. 16, 1988

[0388] In this application for Warp Drive technology, there is a differential current applied. Thus the differential speed of the electrons will, in accordance with relativity, produce differential mass, which will in turn result in a differential graviton release. Thus this invention is very different to previous disclosed inventions, as it is the differential graviton release, which produces the effective warping of space-time, to produce a direct warp drive system, which operates by the warping of space-time.

SUMMARY OF THE INVENTION

[0389] Principles of Warp Drive Systems

[0390] The theoretical understanding of quantum gravity allows the design of warp drive systems from first principles. It is unlikely that gravitons can be controlled in a precise way using current technology. Nevertheless, an understanding of three dimensional space-time and matter, does allow the design of elementary warp drive systems. That is, systems whose propulsion rely on warping space-time as opposed to the ejection of material to provide thrust.

[0391] The background for these systems are already partially understood and quintessence theory allows their further development. For instance, the formation of black holes, represents a crucial step in understanding the mechanisms that underlay gravitational physics and in turn the warping of space-time. The existence of black holes, implies that the warping of space-time allows a powerful system for driving matter. In this instance the space-time lattice would be repelled by gravitons in such a way as to disperse space-time quintessence in a circular fashion, producing an event horizon. Similarly if we suppose that gravitons could be controlled and collimated in a single direction similar to a laser using photons, it would be possible to focus such a graviton beam ahead of an object. This in turn would dissipate the space-time lattice in front of that object, thereby allowing the theoretical potential for what is termed Warp drive.

[0392] Essentially, these are systems whose propulsion relies on warping space-time, as opposed to the ejection of material to provide thrust. This does not, of necessity, mean that superluminal velocities are produced, but that the drive is based on the warping of space-time in accordance with general relativity. However, it would in the future theoretically be possible for an object to achieve speeds greater than that of light, as superluminal velocities produced by the warping of space-time do not contravene general relativity.

[0393] Indeed according to the standard model, if the horizon distance is taken as the maximum distance which light could have travelled, then two points on opposite sides of the Universe are as far apart as ninety times the horizon distance, which indicates that components of the Universe themselves have effectively far exceeded the speed of light.(ref 20a)

[0394] With current technology warp drive systems (not of necessity superluminal) could be achieved by rotating intermediate sized superconducting masses at ultracentrifugational velocities. The release of gravitons could be controlled by differentially governing the electron flow through these masses with the use of powerful electric currents. In turn the differential direction of flow of gravitons would determine the direction of motion through the space time lattice.

[0395] In order to design a mechanism for elementary warp drive we may utilise either a normal conductive material or preferably a superconducting material, or a combination of both. It may be possible to use any shape, such as a disc, cylinder or preferably a sphere. It would also be possible to use dual counter rotating discs to minimize the net angular momentum of the system. In the case of a sphere, this is rotated along its horizontal axis in a clockwise fashion at ultracentrifugational speeds. A differential current is then applied from left to right in such a way as to pass through the entire sphere in this direction.

[0396] The electric charge in the upper half of the sphere would be maximised. The electrons will have a vector in the left to right direction as the sphere spins clockwise. If a maximised current is applied to the sphere in the same direction this will result in a increase in the velocity of the electrons relative to the centre of gravity of the rotating object, due to the flow of current. In turn, according special relativity and to the space-time lattice model, this wilt result in an increase in the relativistic mass if the electrons and in turn by general relativity an increase in the release of gravitons.

[0397] Conversley in the lower half of the sphere the electrons wilt have a vector of motion in the right to left direction due to the spin of the sphere. This will be relativistically slowed by the differential current applied in the same direction as the current above, and hence in the opposite direction to the direction of rotation. The charge can be separately applied and adjusted to ensure that the electrons are relativistically stationary relative to the centre of gravity. In turn this will minimize the relativistic mass and result in a decrease in the release of gravitons for the lower half of the sphere.

[0398] The overall result will be a greater release of gravitons in the upward direction and a lesser release of gravitons in the downward direction. The effect will be enhanced by the use of a multi-phasic current simultaneously applied. This will result in the release of multiphasic gravitons which will disperse space time above the sphere with increase in density below the sphere which will effectively reverse the effects of Earths gravity. Importantly this effect can also be produced with the use radio frequency pulses. This obviates the need for commutator devices. Nevertheless, the radio frequency pulses must be designed to produce a change in the spin of the particle to enhance the release of gravitons in the upward direction, and moreover with current technology theses RF pulses contain too little energy to effect a significant change in the gravitational field.

[0399] With the use of large currents the drift velocity of the electrons could be greatly increased. The use of superconducting devices would greatly enhance the efficiency of such systems as the electrical resistance is virtually eliminated. Thereby allowing large currents to be used with minimum total power output.

[0400] The technological crux of the device is to produce electrons of high speed and hence high relativistic mass in the top half of the sphere, whilst producing low speed and thus low mass electrons at the bottom of the sphere, in accordance with special relativity. The imbalance in the rotating sphere will be continuously present impelling the device upwards. In effect the differential current flow, will produce differential graviton production and in turn, by general relativity, the warping of space-time

TECHNICAL EXAMPLE 1

[0401] A small scale device, which produces warp thrust can be readily constructed using current technology.

[0402] This wilt require a sphere, cylinder or disc of superconducting material. A dual disc either co rotating or counter rotating could also be used, counter rotating discs have the advantage that the total angular momentum is effectively zero. Any of the superconductors may be used such as Ag_2F, C_8K or SnTe. However for their tensile strength and/or magnitude of critical current density (J_c), Nb_3Sn or Ag_2F is recommended. Normal conductive material may be used but due to electrical resistance the power required (see superconductivity theory pg. 9) would be in the order of 10^{19} times greater.

[0403] Taking a sphere of Nb_3Sn, made hollow to reduce the mass of the sphere, with an external radius 0.25 m and an internal radius of 0.20 m; the total volume of Nb_3Sn required would be 3.19×10^4 cm^3. As Nb_3Sn has a density of 7.86 g/cm^3 the total mass of superconducting material would hence be 250 kg.

[0404] This sphere is required to be mounted upon two ultracentrifugational spindles which themselves are on the horizontal axis. The untracentrifugational spindles would be powered to rotate the sphere to produce an enhanced g force, as in a centrifuge.

[0405] The superconductive sphere would require a supercooled jacket of liquid Helium, and would require to be in a vacuum. The power source, motors and refrigeration system should be placed outside the supercooled jacket. In addition these ancillary elements of the device may be either placed outside the system as a whole, or within it, if the device is designed as a self contained vehicle. The device may also be mounted upon vertical rails to experimentally demonstrate vertical lift. (See **FIGS. 1, 2**)

[0406] A high current needs to be applied, by means of a commutator device, to produce a current passing through the sphere. If the negative terminal were placed on the left of the sphere and the positive terminal on the right this would produce electrons flowing from left to right. The commutator device would be split to allow a smaller current to be applied to the lower half of the sphere.

[0407] The power expenditure for this is reduced by using a superconducting material. If the sphere were rotating from left to right i.e clockwise the drift velocity of the electrons would be advanced in the upper half of the sphere, and retarded in the lower half of the sphere by the differential current induced flow of the electrons.

[0408] According to relativity, as defined in the theoretical sections above, it is accepted that the mass of the electrons in the upper half, relative to the centre of gravity, of the sphere can thus be increased by using the standard relativistic formula:

$$m'=m_0/(1-v^2/c^2)^{1/2} \tag{50}$$

[0409] Thus by inducing a relative drift velocity difference, the mass of the electrons at the top of the sphere can be increased, and the mass of the electrons at the bottom of the sphere can be reduced relative to the centre of gravity.

[0410] If the object is set to rotate, centrifugal forces can be used to increase this mass difference. This can be used to increase the net momentum of the object in the upwards direction, to produce upwards thrust.

[0411] Given that there are approximately 10^{23} per cm^3 free electrons in a niobium conductor then in the total sphere there will be approx. $10^{23}\times3.19\times10^{4}$ $cm^3=3.19\times10^{27}$ free electrons in the sphere. If each electron weighs 9.11×10^{-31} kg; then the total mass of free electrons in the upper half of the sphere is 1.453 grams.

[0412] If we take the maximum zero voltage current density (J_c) in Nb_3Sn or another suitable superconducting device as approximately 10×10^{14} Amps/m^2, the drift velocity in the electrons can be calculated. Given that the average surface area of the hollow sphere is approximately 350 cm^2 or 3.5×10^{-2} m^2, then the max current applicable is 3.5×10^{13} Amps. Thus the drift velocity of the electrons would be 6.3×10^{6} m/sec. The velocity of the electrons in the upper part of the sphere would be advanced relative to the centre of gravity. The relative velocity to this centre would be equivalent to the velocity of the sphere plus the velocity of the electrons in the upper half.

[0413] If the drift velocity of the electrons in the lower half were separately, induced by the current so that these electrons were stationary relative to the centre of gravity, those in the lower half of the sphere would be relatively retarded. The current applied to the lower half of the sphere to make the lower electrons, relative to the centre of gravity, stationary (given a rotation rate of 3.14×10^{4} revs/sec) would be 2.46×10^{11} Amps.

[0414] This differential current would allow the electrons to have a differential velocity and in turn a different mass relative to the centre of gravity. The relative velocity would be approximately 6.3×10^{6} m/sec. Using the standard equation for relativity (50) would give a relative mass difference ratio of 2.21×10^{-4}.

[0415] The effective total mass difference between the upper and lower half of the sphere would thus be the mass of the electrons times the relative mass difference which is 1.45 grammes$\times2.21\times10^{-4}=3.2\times10^{-7}$ kg.

[0416] Overall, as the acceleration due to gravity is 9.81 m/sec^2; to produce upwards lift on a sphere of 250 kg in Earth's gravitational field would require a force of about 2,500N. In order to produce in excess of this force the acceleration produced by the ultracentrifuge device would need to be about=8.76×10^{9} m/sec^2. Thus according to the formula $a=(\omega2\pi r)^2/r$ (where the average radius, r of the device is 0.225 m) the rotation rate required would be 3.142×10^{4} revs/sec or approximately 1,880,000 revs/min to produce sufficient acceleration to allow the device to completely self levitate. Thus as F=ma, then the force produced by the device is

$$3.2\times10^{-7}\ \text{kg}\times8.76\times10^{9}\ \text{m/sec}^2=2{,}800\ \text{N}$$

[0417] A detectable anti-gravtiy effect could, however, be realised at much lower spin rates. Standard ultracentrifugation devices can rotate at 600,000 revs/min. Thus even at standard ultracentrifuge speeds the g forces produced would be sufficient to produce approximately 12.8% lift, using these anti-gravity techniques.

TECHNICAL EXAMPLE 2

[0418] For this example we will use a large scale device, which would therefore deliver sufficient thrust to power a vehicle beyond Earth's gravitational field. Under terrestrial conditions the entire devise would be required to be encased in a liquid helium jacket, with an internal vacuum to reduce friction due to air. However, the tatter two constraints need not be in place if the device is to be used in space as, very conveniently, space is both a vacuum, and when shielded from the rays of the sun the ambient temperature is less than that of liquid helium. Indeed the large mass of the superconductor becomes less relevant as weightlessness exists in space, so that the size of the object may be increased substantially.

[0419] Taking a sphere of 1 meter in radius of a superconductive material. The volume is $\frac{4}{3}\pi r^3=4.2\times10^{6}$ cm^3. If the high temperature superconductors are used such as $YBa_2Cu_3O_7$, or $Nd_{1.85}Ce_{0.15}CuO_4$, which are ceramic in nature, the specific density is approximately 3 g/cm^3, Hence the total mass of the sphere would be approximately 12,600 kg or 12.6 metric tonnes. If the standard superconductors are used, for instance Nb_3Sn with a density of 7.86 g/cm^3 the sphere becomes heavier at 33 metric tonnes

[0420] This sphere is required to be mounted upon two ultracentrifugational spindles which themselves are on the horizontal axis. The untracentrifugational spindles would be powered to rotate the sphere to produce an enhanced g force, as in a centrifuge. The sphere would need to be carefully constructed to be exactly balanced in all directions.

[0421] Nevertheless, a high current does still need to be applied, by means of a commutator device, to produce a current. If the negative terminal were placed on the left of the sphere and the positive terminal on the right this would produce electrons flowing from left to right. The power expenditure for this is reduced by using a superconducting material. If the sphere were rotating from left to right i.e clockwise the drift velocity of the electrons would be advanced in the upper half of the sphere, and retarded in the lower half of the sphere by the current induced flow of the electrons. The split commutator device allows a differential current to be applied to the upper and lower halves of the sphere respectively.

[0422] According to the model in the preceding sections this will result in an increase in the mass of the electrons in the upper sphere and hence an increase in graviton production in the upper half of the sphere. Indeed, this model is in agreement mathematically with general and special relativity.

[0423] Given that there are approximately 10^{23} per cm^3 free electrons in a copper conductor then in the total sphere there will be approx. $10^{23}\times4.2\times10^{6}=4.2\times10^{29}$ free electrons in the sphere. If each electron weighs 9.11×10^{-31} kg; then the total mass of free electrons in the upper part of the sphere is 0.191 kg.

[0424] If we take the maximum zero voltage current density (J_c) in Nb_3Sn, or another suitable superconducting device, as approximately 10×10^{14} Amps/m^2, the drift velocity in the electrons can be calculated. Given that the average surface area of the sphere is approximately 1.57×m^2, then the max current applicable is 1.57×10^{15} Amps. Thus the drift velocity of the electrons would be 6.3×10^{6} m/sec.

[0425] At the same time the current in the lower half of the sphere would be adjusted to retard the electrons so that they remain stationary relative to the centre of gravity. If the sphere were rotating at 2.6×10^4 revs/sec this would require a current of 2.04×10^{13} Amps. This differential current would induce a differential velocity in the electrons and in turn a mass difference.

[0426] By inducing a difference of mass as little as one part in a thousand in these electrons we can achieve significant lift. Thus by the above equation if we induce a drift velocity of 6.3×10^6 m/sec (as in technical example 1), given that the velocity of the electrons in the upper part of the sphere would be advanced relative to the centre of gravity and those in the lower half of the sphere relatively stationary; then the relative velocity would be approximately 6.3×10^6 m/sec. Thus between the upper and lower half of the electrons we increase the relative mass of the electrons in the upper half by a factor of 2.21×10^{-4}, as in technical example 1.

[0427] Thus the difference in mass in the upper half of the sphere due to the moving electrons would be 0.191 kg$\times2.21\times10^{-4}=4.22\times10^{-5}$ kg., relative to the lower half electrons. This difference is enhanced by producing a centrifugal force by rotating the sphere.

[0428] If we rotate the large superconducting sphere at 2.6×10^4 revs/sec or 1,560,000 revs/min we can achieve accelerations of 1.33×10^{10} m/sec^2 (given an average radius of 0.5 m) by the formula $a=(\omega2\pi r)^2/r$.

[0429] Thus as F=ma, where m is the relative mass difference of the electrons the thrust produced in the device would be equivalent to:

$$4.22\times10^{-5}\ \text{kg}\times1.33\times10^{10}\ \text{m/sec}^2=5.88\times10^5\ \text{N}$$

[0430] Thus in Earth's gravitational field this force would be capable of levitating 60 metric tonnes.

[0431] The estimated current required to produce the drift velocity of the electrons for this effect would be approx. 1.57×10^{15} Amps. The power usage is given by; $P=I^2R$, under non-superconducting conditions, given that Niobium has a resistivity of 15.2×10^{-8} Ω/m the sphere would have a resistance of approximately 10^{-7} Ω. The power used by a non-superconducting device would thus be 2.46×10^{23} Watts. However, due to superconductivity, under standard theory, the device has zero resistance and would use no power$^{(\text{ref }8)}$. Nevertheless, if we wish to use the model described above for superconductivity (see superconductivity, page 6) there would be a practical power consumption which would nevertheless still be low. Thus the power consumption would be in the order of 1.6×10^{-19} less than the standard power usage, at 3.94×10^4 Watts.

[0432] If Nb_3Sn is used to make the sphere the mass of the sphere would be 33 metric tonnes. If the mass of the ancillary ship were 27 metric tonnes, giving a total of 60 metric tonnes the acceleration produced would be 9.81 m/sec^2. This would be equivalent to the force of gravity on Earth. Thus an artificial gravitational field would be incidentally created which would be exactly equivalent to that on Earth. Thus the device could also be used for the production of artificial gravity.

APPENDIX 1

Particle Physics

In the overall picture, it is generally accepted that there are three major forces; strong, electro-weak and gravity, each mediated by three bosons the, gluon, photon and graviton. These in turn are known to influence three types of particle, the quark, lepton and by General Relativity, space-time itself . Each of these appear to be composed of three particles with multiples of charge of 1/3 and exist in three dimensions of space time, which are themselves in three generations.

The nature of particles thus, may be revealed by their structure which occurs generally in multiples of three. Three quarks in the case of baryons are neccessary to make up a particle such as the proton or neutron. The particles that bind the quarks (gluons) are themselves required, in stable particles, to have three different colour charges, one colour in each dimension, for the particle to exist in three dimensional space-time. Furthermore, there are three generations of leptons an indeed quarks.

Nevertheless, the Standard model itself appears unable to explain the existence of these three generations of particles or the fundamental properties of sub atomic particles. Furthermore, there appear now to be a total of 60 fundamental particles each with their own fundamental properties which are arbitarily defined to fit the data. Furthermore, the Standard model only partially explains the decay process of the each particle and it does not explain their masses accurately.

For instance the mass of the up (u), anti-up (_) down (d) and anti-down (_) quarks are currently estimated at 0.35 Gev each (ref 17) (although some controversy exists about about this basic value). The mass of the proton constituted of three quarks, uud, is 0.9383 Gev, which is only approximately equivalent to the total mass of the three quarks (1.05 Gev).

Furthermore, the very process by which the subatomic particles decay cannot be explained by the "fundamental" constituents, the quarks. Indeed the known hadron decay processes ultimately always end up producing either an electron or positron. Indeed the quarks have not been experimentally seen, suggesting that other particles may underlay their fundamental structure.

Electron Structure

Given the presence of a quasi electron with a charge of 1/3 e (ref 4,5), then three of the quasi electron vortices, as previously described (ref 5), could form an entire electron in three dimensional visible space time. Nevertheless, each would have energy and hence a wave function which would be present in the other vectors. This electron could thus follow the probability functions as described by the Shrödinger wave equation for ψ (otherwise termed as "essence" by Shrödinger).

It is of importance therefore to note that the charge of the electron (e) in Coulombs (C), (where ε_0 is the permittivity of free space), can be derived from first principles by the equation:

$$e = \left[\frac{\varepsilon_0}{3\,(4/3\pi c^3)}\right]^{1/2} = 1.61 \times 10^{-19}\ \mathrm{C} \qquad (6a)$$

Equation (1) has a number of special implications, which have been previously discussed (p 6)

The dimensions of the equation can be readily resolved by considering **each of the three vector dimensions.** The exact dimensions of the equation need to be considered in the light of the nature of space-time itself, and this is fully addressed on pages 82-84. These dimensional equations help explain the nature of matter. Indeed the equation for the electron may underly the structure of the subatomic particles and may be necessary for the full understanding of gravity.

Additionally, the square root sphere structure of the electron accounts for its 1/2 integer spin. This square root structure also forms the basis of the electron pair bonding. According to the above equation (6), the electron will tend to form a "complete" electron sphere, thereby explaining how the presence of pair bonding occurs.

Thus from the equation (3) for the square root structure of the single electron; it is clear that the product of two such spheres will tend to form a complete sphere, where:

$$e^2 = \varepsilon_0/3(4/3\pi c^3) \qquad (6b)$$

In addition, the equation for the quasi electron can be directly derived from eq. 1.

Thus in one dimension, a single quasi electron (q_e) with charge of 1/3e, can be mathematically represented, (where the permittivitty of free space for each quasi electron is $\varepsilon_{qe} = [\varepsilon_0/3^3]^{1/2}$, by the equation :

$$q_e = \varepsilon_{qe}/(4/3\pi c^3)^{1/2} = 1/3e \qquad (6c)$$

Thereby accounting for the experimental observation of the 1/3e charge of the quasi electron(ref 4,5). Overall knowing the structure of the quasi electron may lead to the knowledge of the structures of the the other subatomic particles such as the quarks.

First Generation Quark Structure

From these observations we may now examine the derivation of the mathematical nature of the proton and in turn the structure of the quarks. Using the above equations (eq. 6) enables a far more accurate derivation of the mass of quarks from first principles.

To do so requires calculating the ratio of the mass of the electron ($m_e = 0.511$ Mev) to the mass of the proton ($m_p = 938.3$ Mev)

Thus $m_e/m_p = 0.511/938.3 = 5.44 \times 10^{-4}$

and $m_e/m_p = 5.44 \times 10^{-4} = (3\pi/c^{1/2})$

Intruigingly, the term $(3\pi/c^{1/2})$ mathematically determines the ratio of the mass of the electron (m_e) to the proton (m_p). Indeed it is this ratio that also leads to the mathemaical derivation of the structure of the quarks

Given the mass of the proton is; 938.3 Mev, then according to the Standard Model, as there are three quarks in the proton (uud) of virtually equal mass, then the effective mass of each quark would be more accurately given as 312.8 Mev.

Thence, the structure of the quarks can now be defined by the ratio of the masses of the quasi electron to the quark. If the mass of the quasi electron is given as one third the mass of the electron

$$m_{qe} = 0.511 \text{ Mev} \div 3 = 0.17033 \text{ Mev}$$

Then the ratio of the mass of the down quark (d), to the quasi electron is:

$$0.17033 \text{ Mev}/ 312.8 \text{ Mev} = 5.44 \times 10^{-4}$$

We also find that this same ratio of the mass of the quasi electron to the mass of the down quark (m_d) is mathematically equivalent to $3(\pi/c^{1/2})$, thus:

$$m_{qe}/m_d = 5.44 \times 10^{-4} = 3(\pi/c^{1/2})$$

From here the equation for the charge and structure of the down quark can be accurately defined by combining the equation for the structure of the quasi electron $q_e = \varepsilon_{qe}/(4/3\pi c^3)^{1/2}$ and the ratio of the masses of the quasi electron to the down quark (19); hence

$$d = \varepsilon_{qe}.m_d/m_{qe}.(4/3\pi c^3)^{1/2}.3(\pi/c^{1/2})$$

Hence in short form

$$d = (4/3\pi c^3)^{1/2}.3(\pi/c^{1/2}) \qquad (16)$$

Giving the charge of the down quark as -1/3; and its estimated mass as 312.8 Mev.

Thus not only can the electron charge be derived from the equation for three spheres each with a radius of c (equation 3) ; but the mass, charge and internal structure of the down quark can also be derived from the term $3(\pi/c^{1/2})$.

Furthermore, the significance of the term $3(\pi/c^{1/2})$ in this equation, is revealed by the Shrödinger wave equation. Thus $(\pi/c^{1/2})$ is none other than the solution to the Shrödinger wave equation for the amplitude of an electron confined in a space with radius c (ref 6). If c is the space defined by the equation for the structure of the quasi electron. Then the standard Shrödinger equation for an object confined in a space c is given by the following standard calculation (ref 8):

$$E\psi(x) = -\frac{h^2}{2m} . \frac{d^2\psi(x)}{dx^2}$$

If one of the dimensions of space has a length 2L the amplitude can only be non zero between $x = 0$ and $X = 2L$ and the standard solution for the amplitude can be determined by using the constant (A) where:

$$A = (1/L^{1/2})$$

Thus in one dimension the solution to the Shrödinger wave equation for the amplitude of oscillation is conventionally given by (ref 8) :

$$\psi(x) = (\pi/L^{1/2}) \quad \sin x/L$$

Substiuting L for c gives the one dimensional equation (when $\sin x/L = 1$) as $\pi/c^{1/2}$. Thus at 90°to the dimensional confinement of the quasi electron, the standard solution to the Shrödinger wave equation yields an amplitude of $\pi/c^{1/2}$, which in three dimensions gives:

$$3(\pi/c^{1/2}) \qquad (22)$$

Thus the term $3(\pi/c^{1/2})$ is not only the ratio of the mass of the electron to the proton but is also none other than the standard solution to the Shrödinger wave equation for an object confined in a space c $^{(\text{ref } 8)}$.

From here the charge and structure of the up quark (u) can now be derived in a similar way to that of the up quark from the mass of two quasi positrons [m_{qp} = 2(0.170 Mev)] and the mass of the up quark (m_u) by the equation,

$$2m_{qP}/m_U = 2(5.44 \times 10^{-4}) = 2(3\pi/c^{1/2})$$

Thus:

$$u = \varepsilon_{qe} .2m_{qP}/m_u.2^{+}(4/3\pi c^3)^{1/2}.(3\pi/c^{1/2})$$

Hence in short form

$$u = 2^{+}(4/3\pi c^3)^{1/2}.(3\pi/c^{1/2}) \qquad (17)$$

Giving the charge of the up quark as +2/3, and its mass as 312.8 Mev

Overall the mathematical structure of all the particles can be shown to be derived from the quasi electron. Thus, the first generation particle structures can now be derived from first principles. This includes the quasi electron (qe) and electron (e), from which the quarks (u,d) and in turn the proton (p) respectively are derived.

Thus the first generation of particles of the Standard model are given in short form as:

$$qe = {}^{-}(4/3\pi c^3)^{1/2} \qquad (6a)$$

$$e = 3^{-}(4/3\pi c^3)^{1/2} \qquad (6)$$

$$d = {}^{-}(4/3\pi c^3)^{1/2}.3(\pi/c^{1/2}) \qquad (16)$$

$$u = 2^{+}(4/3\pi c^3)^{1/2}.3(\pi/c^{1/2}) \qquad (27)$$

The respective force binding particle, the gluon, for the first generation of particles is thus given in short form as:

$$g = 3(\pi/c^{1/2}) \qquad (22)$$

According to these equations, it is apparent that the down and up quarks appear be constituted from quasi electrons and three component gluons, and are themselves not fundamental particles.

Indeed, from these observations it is clear that the structure of the electron, may underly the structure of all the elementary particles and nucleons, as it forms a "perfect sphere" based on c. As will also be seen later, as this structure forms the basis of matter, it may itself underpin the theory of gravity. Furthermore, these obsevations will allow the mathematical estimation of the mass and size of the elementary particles, including the second and third generation particles

Second and Third Genration Lepton Structure

Thus the structure of the muon (μ) can also be derived from the ratio of the mass of the electron (m_e) and the mass of the muon (m_μ):

$$m_e/m_\mu = 4.7 \times 10^{-3} = \pi/c^{1/3}$$

Thus $$\mu = \varepsilon_0^{1/2}.m_e/m_\mu. 3^{-}(4/3\pi c^3)^{1/2}.(\pi/c^{1/3})$$

Where the charge of the muon is in this equation equivalent to that of the electron e. In this case ($\pi/c^{1/3}$) can be considered to represent a specific high energy photon. Thus the structure of the muon, written in short form is:

$$\mu = 3^{-}(4/3\pi c^3)^{1/2}.(\pi/c^{1/3}) \qquad (14)$$

Moreover the structure of the tauon can be calculated from the ratio of the mass of the electron and that of the Tauon (1.79 Mev);

Thus $$0.511 \text{ Mev}/1.79 \text{ Gev} = 2.85 \times 10^{-4}$$

$$m_e/m_\tau = (\pi/c)^{1/3}.(\pi/c)^{1/9} = 2.85 \times 10^{-4}$$

As the charge of the tauon is equivalent to the charge of the electron, hence the structure of the Tauon is given by the above equation

$$e_\tau = \varepsilon_{qe}.m_e/\ m_\tau.3^{-}(4/3\pi c^3)^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9} = e$$

This equation accurately predicts the charge -1; and mass of the Tauon (~1.78 Gev) (ref 14). Thus the structure of the Tauon can in short form be given by the equation

$$\tau = {}^{-}3(4/3\pi c^3)^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9} \qquad (15)$$

Overall the mathematical structure of all the particles can be derived from the quasi electron. Thus, the particle structures can now be derived from first principles. This includes the quasi electron (qe) and electron (e), from which the quarks (u,d) and in turn the proton (p) respectively are derived. The general structure of the force carrying partilcles the photon (γ) and the gluon (g) can be given. It will also intriguingly be possible to derive the structure of the charm (c), beauty (b, or bottom) and truth (t or top) quarks directly from the sructure of the muon (μ) and Tauon (τ).

The calculations underlying these equations can further accurately reflect their measured values, particularly if the effects of gravity are taken into account (see Quantum Gravity and the Charge of the Electron.p 30). In addition the neutrino has not been included in the equation as its mass is considered to be very small. The mathematical proof of these short form equations nevertheless lies in the fact that they can closely identify the charge and the masses of these particles, from first principles, as in equations (6, 13-27). (ref 17)

Second and third generation Quark Structures

From here it is possible to derive the basic structure of the remaining quarks including the strange (s) quark.

Thus the ratio of the masses of the quasi electron (m_{qe} = 0.17033 Mev) and the strange quark (m_s = 0.555 Gev) are given by the equation:

$$m_{qe}/m_s = 0.17033\ \text{Mev}/\ 0.555\ \text{Gev} = 3.07 \times 10^{-4}$$

Furthermore the structure of the gluon in the strange particle, can now be accurately derived by the term; $3(\pi/c)^{1/2}$,(n.b. change of brackets in the gluon term).

$$m_{qe}/m_s = 3.07 \times 10^{-4} = 3(\pi/c)^{1/2}$$

Thus the equation for the charge and structure of the strange quark (s) is:

$$s = \varepsilon_{qe}.m_{qe}/m_s\ ^{-}(4/3\pi c^3)^{1/2}.3(\pi/c)^{1/2} \qquad (18)$$

This can be written in short form as:

$$s = {}^{-}(4/3\pi c^3)^{1/2}.3(\pi/c)^{1/2}$$

Giving the strange quark a charge of -1/3 and a mass of 0.555 Gev, in agreement with current estimates of its mass - 0.55 Gev (ref 14). This again shows that strange quark is derived from a quasi electron and a gluon.

Thus given that the particle Ω^- is made of three strange quarks (sss) we may derive its mass as 3 x 0.555 Gev = 1.67 Gev, which is in accurate aggreement with its known mass of Ω^- = 1.67 Gev (ref 17)

From here it is possible to define the structure of the other quarks, using the same first principles. As the charmed quark (c), beauty (b, otherwise termed bottom) and the truth (t, otherwise termed the top quark), clearly belong to the second and third generation of particles, they should be mathematically based on the formula for the second and third generation lepton particles, specifically the muon and tauon.

Indeed the charm derives from the second generation of particles and therefore mathematically does qappear to contain the basic muon structure, as given by the equation:

$$\mu = 3(4/3\pi c^3)^{1/2}.(\pi/c^{1/3}) \qquad (14)$$

As before, the ratio of the masses of the quasi electron and that of the charm quark gives the equation from the structure of the charm (c).Thus the structure of charm can be determined from the ratio of the mass of two quasi electrons; m_{qe} = 2(0.17033) Mev, and the mass of the charmed quark (m_c = 1.518 Gev)

Thus if: $2m_{qe}/m_c = 2(0.17033\ \text{Mev})/1.518\ \text{Gev} = 2(1.122 \times 10^{-4})$

and $2m_{qe}/m_c = 2(1.122 \times 10^{-4}) = 2(\pi/c^{1/3}).(\pi/c^{1/4})$

Then the structure of the charm quark (c) is:

$$c = \varepsilon_{qe}.2m_{qe}/m_c\ .2^{+}(4/3\pi c^3).^{1/2}(\pi/c^{1/3}).(\pi/c^{1/4})$$

or in short form

$$c = 2^{+}(4/3\pi c^{3})^{1/2}.(\pi/c^{1/3}).(\pi/c^{1/4}) \qquad (19)$$

Thus the charmed quark has a charge of +2/3 and a mass of 1.518 Gev in accordance with the previous approximate estimate of its mass ~ 1.5 Gev. (ref 17) and is derived from a muon and a higher order gluon. This gluon itself $(\pi/c^{1/4})$, is the solution to the Shrödinger wave equation for the amplitude of an electron confined in a space of length $c^{1/2}$ (ref 8). Thus this gluon now exactly matches the amplitude of the quasi electron.

Furthermore, from this we can deduce the mass of the particle the J/ψ, whose structure is predicted to consist of a charm and anticharm particle in orbit around each other, with a minimum mass (including orbital energy) of ~ 3.1 Gev.

From here we can in a similar fashion determine beauty (b). To be consistant, as beauty is a third generation quark it should be defined by the component structure of the Tauon. In this case, this is the smaller component of the Tauon, which is mathemtaically represented by:

$$3(4/3\pi c^{3})^{1/2}.(\pi/c^{1/9})$$

Indeed the structure can again be determined by the ratio of the mass of the quasi electron electron (m_{qe}) to beauty (m_b). Such that the ratio can be given by the equation

$$m_{qe}/m_b = 3.673 \times 10^{-4} = (\pi/c^{1/9}).(\pi/c)^{1/2}$$

Thus the structure of beauty is given by the equation

$$b = \varepsilon_{qe}.m_{qe}/m_b.(4/3\pi c^{3})^{1/2}.(\pi/c^{1/9}).(\pi/c)^{1/2}$$

To confirm this structure, the mass of the beauty quark can be given by the following calculation

$$m_{qe}/m_b = 3.673 \times 10^{-4} = 0.17033 \text{ Mev} / 4.64 \text{ Gev}$$

and

$$m_{qe}/m_b = 3.673 \times 10^{-4} = (\pi/c^{1/9}).(\pi/c)^{1/2}$$

Thus the short form of beauty is:

$$b = {}^{-}(4/3\pi c^3)^{1/2}.(\pi/c^{1/9}).(\pi/c)^{1/2} \qquad (20)$$

Thus giving beauty a charge of -1/3, and a mass of 4.64Gev, which is in agreement with its current estimated mass of ~ 4.7 Gev (ref 17).

To complete the structure of the quarks, we can finally proceed to deduce the truth. As the top quark or truth (t) belongs to the third generation of quarks, it is also based on the structure of the Tauon. Thus mathematically the truth, primarily consists of the third generation, tauon.

$$\tau = 3(4/3\pi c^3)^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9} \qquad (15)$$

The geometrical structure can be confirmed from the mathematical ratio of the mass of the electron to mass of truth (m_t), hence the equation for the top quark is given by the ratio of the mass of the electron to mass of the truth .

Thus as $m_t = 176$ Gev

and as $m_e = 0.511$ Mev

$$m_e/m_t = 0.511 \text{ Mev}/176 \text{ Gev} = 2.89 \times 10^{-6}$$

and

$$m_e/m_t = 2.89 \times 10^{-6} = (\pi/c)^{1/3}.(\pi/c)^{1/9}.(\pi/c)^{1/4}$$

As each quasi positron is associated with each of the gluon complexes, then the equation for truth is thus predicted by the equation:

$$t = 2(4/3\pi c^3)^{1/2+}.(\pi/c)^{1/3}.(\pi/c)^{1/9}.(\pi/c)^{1/4} \qquad (21)$$

Which gives the mass of the truth as 176 Gev and a charge of +2/3e. Which is in agreement with the known mass of the truth; 176 ± 12 Gev; the most accurate estimate of the mass of the truth quark being; 175.6 Gev.(ref 22)

Thus the basic structure of the truth, is that of a pair of quasi anti-tauons complexed with a gluon moiety which has an amplitude that, according to the Shrödinger wave equation (3), exactly matches the amplitude of the quasi electron (ref 8).

Mathematically the probability of arriving at all such tightly conformed equations (3, 16-30), the particles being related only to π and c and its specific powers, **by chance would have odds of millions to one against.!** Furthermore these mathematical structures are derived from none other than solutions to the Shrödinger wave equation itself (ref 8).

Moerover, the structures of the second and third generation particles, the muon (μ), and charm (c); tauon (τ) and truth (t) quarks have a **notable symmetry**, with their masses and charges accurately given by the following short form equations:

$$\mu = 3^{-}(4/3\pi c^{3})^{1/2}.(\pi/c^{1/3}) \tag{14}$$

$$c = 2^{+}(4/3\pi c^{3})^{1/2}.(\pi/c^{1/3}).(\pi/c^{1/4}) \tag{19}$$

$$\tau = 3^{-}(4/3\pi c^{3})^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9} \tag{15}$$

$$t = 2^{+}(4/3\pi c^{3})^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9}.(\pi/c)^{1/4} \tag{21}$$

Hence, from these equations it can be deduced that the fundamental structure of the quasi electron probablistically underpins the mathematical structure of the fundamental particles, and that these structures are all related to one another either by complexing with a photon $[(\pi/c)^{1/3}]$ which matches the frequency of the quasi electron or a gluon $[(\pi/c^{1/4})]$ which according to the Shrödinger wave equation accurately matches the amplitude of the quasi electron. This explains the fundamental observations that final decay products of hadrons always lead to the production of an electron or positron and explains why quarks have not been individually seen.

Particle Decay and the Electroweak Force.

In order to corroborate the estimated quark structures these structures need to explain in detail the pattern of decay of the quarks themselves. We are thus required to explain particle decay from first principles including the structures which are formed in these decays, such as the mediator of the electro weak force; the Intermediate Vector Boson. To see if this is possible the decay of the truth (t, top quark) will be examined. According to experiment the truth quark splits into two particles, beauty (b, bottom quark) and the intermediate vector boson (W^{+}). It is apparent that the truth may yield beauty.(ref 22)

Thus:

$$2^{+}(4/3\pi c^{3})^{1/2}.(\pi/c)^{1/3}.(\pi/c)^{1/9}.(\pi/c)^{1/4}=t$$

$$\Rightarrow \quad (4/3\pi c^{3})^{1/2}.(\pi/c^{1/9}).(\pi/c)^{1/2} \quad = b$$

Thus the two gluon structures, $(\pi/c)^{1/4}$; in the truth combine to form the more energetic gluon, $(\pi/c)^{1/2}$; present in beauty, thus:

$$2(\pi/c)^{1/4}\Rightarrow(\pi/c)^{1/4}.(\pi/c)^{1/4}\_\;(\pi/c)^{1/2}$$

and the photon term, $(\pi/c)^{1/9}$; decays into the less energetic photon $(\pi/c^{1/9})$ present in beauty. Thus the structures in the truth account for the structures in beauty, and are produecd via the production of a quasi electron and quasi positron.

The remaining terms are thus 3 quasi positrons, two high energy photons and a remaining low energy photon

$$3^{+}(4/3\pi c^{3})^{1/2}$$

and

$$2(\pi/c)^{1/3}$$

and

$$(\pi/c)^{1/9}$$

There is also a very considerable amount of energy remaining, the energy difference between beauty (b) and truth (t) being ~ 170 Gev.

This energy difference allows the transformation of the two high energy photons and the low energy photon to two intermediate vector photons, given by the equation.

$$2(\pi/c^{1/6})^{6}$$

This leads to the formation of the intermediate vector boson (W^{+}), which is the mediator of the electroweak nuclear force.

$$W^{+}=3^{+}(4/3\pi c^{3})^{1/2}.2(\pi/c^{1/6})^{6} \qquad (24)$$

which is also equivalent to

$$W^+ = 3^+ (4/3\pi c^3)^{1/2}.2(\pi/c^{1/6})^3.(\pi/c^{1/6})^3$$

This probable structure for the (W^+), can again be confirmed by the ratio of the mass of the electron to the intermediate vector boson (W^+), with an estimated mass of 80 Gev $^{(\text{ref } 17)}$. Thus the ratio of the masses is given by

$$m_e/m_{W+} = 0.511 \text{ Mev}/ 80 \text{ Gev} = 6.4 \times 10^{-6}$$

and

$$m_e/m_{W+} = 6.4 \times 10^{-6} = 2(\pi/c^{1/6})^6$$

Thus

$$W^+ = \varepsilon_{qe}\text{-}m_e/m_{W+}.3^+(4/3\pi c^3)^{1/2}.2(\pi/c^{1/6})^6$$

thus in short form:

$$W^+ = 3^+ (4/3\pi c^3)^{1/2}.2(\pi/c^{1/6})^6$$

The true elegance of the structure of the intermediate vector boson can now be further explored. The W^+ can be considered to represent a unification of the electromagnetic force and the weak force, in keeping with the theoretical predictions of Salam and Weinberg for the nature of the electroweak force. Thus, the intermediate vector photons can either decay leptonically or via gluons; as is demonstrated by the following interconversions.

$W^+ = 3^+ (4/3\pi c^3)^{1/2}.2(\pi/c^{1/6})^6$ _ $3^+ (4/3\pi c^3)^{1/2}.2(\pi/c^{1/6})^3.(\pi/c^{1/6})^3$

If we examine the further decay of the three dimensional photon structure, $(\pi/c^{1/6})^3$; we have:

$(\pi/c^{1/6})^3 \Rightarrow [(\pi/c)^{1/6}]^3$ _ $(\pi/c)^{1/2}$

Where the term $(\pi/c)^{1/2}$ is none other than the term for a first generation gluon.

Thus the W^+ can either decay leptonically or into first generation quarks where it can yield an up (u) and an anti-down quark (_), thus:

$$W^+ = 3^+ (4/3\pi c^3)^{1/2}.2(\pi/c^{1/6})^3.(\pi/c^{1/6})^3 \Rightarrow 3^+(4/3\pi c^3)^{1/2}.2[(\pi/c)^{1/6}]^3.[(\pi/c)^{1/6}]^3$$

And

$3^+(4/3\pi c^3)^{1/2}.2[(\pi/c)^{1/6}]^3.[(\pi/c)^{1/6}]^3$ _ $3^+(4/3\pi c^3)^{1/2}.2(\pi/c)^{1/2}.(\pi/c)^{1/2}$

thus W^+ decays to:

$$\Rightarrow \quad 2^{+}(4/3\pi c^{3})^{1/2}.3(\pi/c^{1/2}) = u$$

and

$$\Rightarrow \quad {}^{+}(4/3\pi c^{3})^{1/2}.3(\pi/c^{1/2}) = \_d$$

Leptonically the W^{+} decay yields the standard products including the positron the neutrino (v), and energy in the form of photons thus

$$W^{+} = 3^{+}(4/3\pi c^{3})^{1/2}.2(\pi/c^{1/6})^{6} \_ 3^{+}(4/3\pi c^{3})^{1/2}.2(\pi/c^{1/6})^{2}.(\pi/c^{1/6})^{2}.(\pi/c^{1/6})^{2}$$

and

$$\Rightarrow \quad 3^{+}(4/3\pi c^{3})^{1/2}.2[(\pi/c)^{1/6}]^{2}.[(\pi/c)^{1/6}]^{2}.[(\pi/c)^{1/6}]^{2}$$

$$\_ \quad 3^{+}(4/3\pi c^{3})^{1/2}.2(\pi/c)^{1/3}.(\pi/c)^{1/3}.(\pi/c)^{1/3}$$

Thus W^{+} may also decay into the positron the neutrino (v), and energy in the form of photons thus:

$$\Rightarrow \quad 3^{+}(4/3\pi c^{3})^{1/2} = e^{+}$$

and

$$\Rightarrow \quad v$$

and

$$n(\pi/c)^{1/3}$$

Thus according to standard experimental observations the truth quark yields the beauty quark and the intermediate vector boson. In turn from these observations we may elegantly reveal the structure of truth and beauty and the intermediate vector boson and its decay pathways from first mathematical principles. (ref 18)

Gluon Structure and Force Characteristics

There are in the Standard model (or in this modification) three colour charges for the gluons and quarks, each of these represents each of three vectors x, y and z which can arise in different combinations. Thus the three gluon colours are required to be together (one in each dimension x, y and z) in baryons to form a three dimensional objects. There are also noted to be 8 gluons, these in turn gives rise to all the known baryons and mesons

The structure of these gluons have been previously mathematically identified, and this structure mathematically represents a helical ringlet. These are as previously given: $(\pi/c)^{1/2}$; $(\pi/c)^{1/4}$; $(\pi/c^{1/2})$; $(\pi/c^{1/4})$ [see eq. 25- 25c]

These four mathematical structures and their antigluons now readily account for the eight gluons known to exist, these in turn account for the structure of all the quarks as given by equations 3, 15-30, which in turn give rise to all the baryons and mesons as described by the Standard model.

Recent studies show that the proton conventionally consisting of the "fundamental" quarks (uud); can by bombardment with high energy electrons produce a Kaon which consists of an anti-up and a strange quark (s_). As the standard model predicts quarks are fundamental, the proton should not contain a strange quark. The conventional explanation for this resides in the proposal that the proton contains virtual strange particles. Indeed to explain these new observations each proton is now postulated by some physicists to contain 21 or more quarks, 3 of which are real and 18 or more which are required to be virtual! (ref 23).

In the revised Standard model presented here, the process by which a Kaon is produced is readily understood by the structural interconversion of the gluon in the up quark $(\pi/c^{1/2})$; to the gluon in the strange quark $(\pi/c)^{1/2}$,(n.b change of brackets)

Furthermore the most recent experiments on the internal structure of the proton has shown that gluons can seperate and recombine. This surprising recent observation actually arises from first principles when the mathemtatical structure of the gluon is understood. Thus mathematically the gluon structures may easily recombine and separate by the equation.(ref 24)

$$(\pi/c)^{1/2} = (\pi/c)^{1/4}.(\pi/c)^{1/4}$$

Hence this mathematical structure of the gluon allows the observed "recombination" and separation to occur in a way which is readily understood.

In addition, the structure of the gluons can be explained on the basis that these structures match the wave function of the quasi electron, thus the gluons match the amplitude of the electron as given by the Shrödinger wave equation.(ref 8)

Furthermore, the equations for the gluon present in the quark can explain their force characteristics. In the case of the gluon component $(\pi/c^{1/2})$; which mathematically represents a helical ringlet; if the direction vector is x, then the axis of spin would need be 90° to this, in the y vector in order to match the amplitude of vibration of the quasi elelctron/ positron. Thus this spin vector is known to be the same as that of electrons. This would account for the particle binding characteristics of the gluon force to the quasi electron. Given that the gluon would mathematically require the same spin axis as that of the quasi electron or positron, the gluon would be strongly associated with these particles and the force required to part them would increase with distance, which explains the characteristics seen experimentally with the gluon force.

Moreover, as will be shown, the photonic component of the subatomic particles given in the above equations matches exactly the frequency of rotation of the electron.

Nucleon Structure

The mass (m_p) and the internal mathematical structure of the proton can now be directly calculated form the quarks. Thus the structure of the proton according to the Standard model derives the combination of 2 up quarks and one down quark (p = uud). As each quark has an estimated mass of 312.8 Mev (see eq. 13) then the proton (p) has in accordance with the Standard model a mass of 3 x 312.8 = 938.3 Mev and a charge of +1, and may be given by the mathematical structure of the up and down quarks according to eq. 16,17; and is thus given by:

$$p = \begin{array}{c} 2^{+}(4/3\pi c^{3})^{1/2}.(3\pi/c^{1/2}) \\ {}^{-}(4/3\pi c^{3})^{1/2}.(3\pi/c^{1/2}) \\ 2^{+}(4/3\pi c^{3})^{1/2}.(3\pi/c^{1/2}) \end{array}$$

Which, gives the proton a net charge +1 and a mass of 938 Mev.

Fifteen component gluons are required to be present in the proton, three gluons associated with each quasi electron particle.

Therefore the structure of the proton can be mathematically derived by combining the structure of the quasi electrons and the term $(\pi/c^{1/2})$. Thus the structure of the neutron and indeed the overall structure of the nuclei can be determined.

Similarly the structure of the neutron is given by the Standard model (n = udd), which can be written in short form as:

$$n = \begin{array}{c} {}^{-}(4/3\pi c^{3})^{1/2}.3(\pi/c^{1/2}) \\ 2^{+}(4/3\pi c^{3})^{1/2}.3(\pi/c^{1/2}) \\ {}^{-}(4/3\pi c^{3})^{1/2}.3(\pi/c^{1/2}) \end{array}$$

The mystery of the stability of the neutron may now be addressed. A neutron outside the nucleus has a half life of approximately 6 seconds. Inside the nucleus however, the stability of the neutron, provides the atom with its stability. The three dimensional structures described may now provide the clues to this stability.

The compostion of the quarks now logically explains the apparent "fluid" characteristics of the subatomic particles, and some free exchange of the quasi electrons and gluons would be expected to occur within a nucleus.

This would occur to to give the structures stability and this in turn would allow the decresed binding energies seen in these structures. As has been shown by the metric tensor structure of matter (eq. 4-6), the preferred conformation is a 3 x 3 structure.

This can be acheived by donating a quasi electron and a quasi positron along with three associated gluons each; from the proton structure to that of the neutron. The proton would then contain three positrons and a total of nine gluons

The stable nuclear proton conformation would now be :

$$p = 3^{+}(4/3\pi c^{3})^{1/2}.3(\pi/c^{1/2}) \qquad (13)$$

This can form a stable 3 x 3 conformation.

Thus the probable structure of the stable nucleonic neutron (n), would now contain a total of three quasi positrons and three quasi electrons along with their respective eighteen gluons and is represented by an equation, which also forms a 3 x 3 conformation:

$$n = \begin{matrix} {}^{+}(4/3\pi c^{3})\downarrow^{1/2}.2(3\pi/c^{1/2}).{}^{-}(4/3\pi c^{3})\uparrow^{1/2} \\ {}^{+}(4/3\pi c^{3})\downarrow^{1/2}.2(3\pi/c^{1/2}).{}^{-}(4/3\pi c^{3})\uparrow^{1/2} \\ {}^{+}(4/3\pi c^{3})\downarrow^{1/2}.2(3\pi/c^{1/2}).{}^{-}(4/3\pi c^{3})\uparrow^{1/2} \end{matrix} \qquad (26)$$

Viewed in three dimensions the configuration will allow the positron components of the neutron to be placed interiorly and the electron components exteriorly, in keeping with experiments that suggest that the neutron core is positive an the exterior is negative. This polarised structure in turn will enable the neutron to bind the protons of the nucleus together.

Alpha Particle Structure

Importantly it is now possible to **derive the mathematical structure of the helium nucleus** (α particle) containing two protons and two neutrons, along the same lines. The proposed basic conformation is again 3 x 3.

$$\alpha = \begin{array}{l} [3(4/3\pi c^3)]\downarrow^{1/2+}.2(3\pi/c^{1/2}).\ [3(4/3\pi c^3)]\uparrow^{1/2-} \\ [3(4/3\pi c^3)]\uparrow^{1/2+}.2(3\pi/c^{1/2}).\ [3(4/3\pi c^3)]\downarrow^{1/2+} \\ [3(4/3\pi c^3)]\downarrow^{1/2-}.2(3\pi/c^{1/2}).\ [3(4/3\pi c^3)]\uparrow^{1/2+} \end{array} \quad (27)$$

This mathematical expression for the structure of the α particle allows the **calculation of its binding energy from first principles!** Each pair of particles is still associated with the equivalent of 18 gluons each, that is $3^{1/2}.2(3\pi/c^{1/2}).3^{1/2}$. However, the internal structure has altered, to effectivly reduce the number of quasi electrons. Thus as a result of triplet pairing, which has occurred in order to make up the helium nucleus, we are left with a reduced number quasi electrons.

Hence, the number of quasi electrons is reduced by a factor of 3 as a result each of the three pairings of the six quasi electron groups. This means the reduction in the equivalent number of quasi electron masses (including the electrical kinetic energy of the complex vectors) is effectively 3^3 x 6. Each of these weighs 1/3 the rest mass of the electron. The total energy therefore liberated is equivalent to 27 x 6 quasi electron masses (approximately 27.5 Mev). This agrees with the difference in mass between the constituent protons and neutrons and the rest mass of the helium nucleus, thus accounting for the binding energy of the helium nucleus.

This structure is also important for the understanding of the internal structure of atomic nucleii, The alpha particle appears to form a natural sphere as indicated by the metric tensor structure (see eq. 6-9). In turn the basic structure of atomic nucleii appear to form in multiples of alpha particles; the carbon atom for instance forms from three, separate, such helium nuclei spheres.

Furthermore knowledge, of the structure of the α particle may be of considerable importance in the understanding **of nuclear fusion** and the eventual harnessing of this technology.

Neutrino Structure

Whilst it has been possible to derive the structure of the fundamental particles form their known masses, the mass of the neutrino remains uncertain. However, recent evidence does support the contention that the neutrino does indeed have rest mass, which is a starting point.

If the neutrino does have rest mass this suggests it has a basic spherical structure like the electron, and will therefore be subject to relativistic changes in mass. Again experiment confirms this relativistic component.

It is also reasonably certain that whilst the neutrino mass is smaller than that of the electron, its size is also likely to be smaller, and on the basis of what is known of the radius of the electron (see Particle Spin and Size) the essential radius is also likely to be related to c.

Indeed as the electron radius is 1/c x 2/spin, where the intrinsic radius is 1/c. Then by deduction the neutrino radius is related to $1/c^2$. Thus the most likely equation for the neutrino is:

$$e\nu = \left[\frac{\varepsilon_0}{3\left[4/3\pi(c^2)^3\right]}\right]^{1/2} = \left[\frac{\varepsilon_0}{3\left[4/3\pi c^6\right)}\right]^{1/2} \qquad (6d)$$

This of course endows the neutrino with a very small charge of: 9.71×10^{-32} C. (which reduces to 9.42×10^{-63} C, when the neutrino forms a Cooper neutrino pair) Nevertheless, if the neutrino has mass, like all other elementary particles we should not be surprised if it also has a charge. Furthermore we may use the above formula to estimate the neutrino mass itself.

Without concerning ourselves too much at this point about the exact origin of the nature of the mass of the electron (which is addressed in chap. Quintessence and Electron Structure). It is reasonable to postulate that, if the radius is related to $1/c^2$ then the number of quintessences in the neutrino will be equivalent to the square root of the number of quintessences in the electron. Indeed this means that the number of quintessences in the electron neutrino is 1.925×10^{10} quintessences. Knowing the mass of quintessence; 2.4575×10^{-51} kg, gives us the mass of the electron neutrino (with an estimated error range of: x/÷ 3), as:

$$m_{ve} = 4.731 \times 10^{-41} \text{ kg} = 0.0000265 \text{ ev}$$

We may also deduce the masses of the mu neutrino and the tau neutrino from first principles. Interestingly we also know that the μυ and the ταυ neutrino can convert an electron to a muon or tauon respectively (if the neutrino has sufficient relativistic energy). So it is likely that the geometric elements present in the muon and tauon are also present in their respective neutrinos. Thus the short inverted form equations are given by:

$$\nu_\mu = 3^{-}(4/3\pi c^6)^{1/2}/(\pi/c^{1/3}) \qquad (6d)$$

$$\nu_\tau = 3^{-}(4/3\pi c^6)^{1/2}/(\pi/c)^{1/3}.(\pi/c)^{1/9} \qquad (6d)$$

These mathematical suffixes are merely the same geometric components, which combine with the quasi electron to form the muon and tau. In the same way the ratio of the masses of the muon and tau to the electron, were deduced from first principles (see Fundamental Forces and Particle Structure) these equations predict the respective masses of these neutrinos (with an error range of x/÷ 3), as:

$$\nu_\mu = 0.00546 \text{ ev} \quad \text{and} \quad \nu_\tau = 0.0927 \text{ ev}$$

Indeed recent evidence from the super Kami0kande experiment supports these observations with regard the tau neutrino, and places its mass in the range 0.1- 0.03 ev.

Quintessence and Internal Electron Structure

The reason for the value for the mass of the electron, has till now remained a mystery. The internal structure of the electron is therefore of considerable importance as it may elucidate the underlying reason for the mass of the electron. In turn we may derive the mass of all the particles from first principles, as these themselves derive from the structure of the electron (see previous chapter; Fundamental Forces and Particle Structure). Additionally, it may also be possible to estimate the radius of quintessence, from the structure of the electron. Quintessence in turn is fundamental to the formulation of quantum gravity.

We may begin with the formula for the charge of the electron

$$e = \varepsilon_{qe}/3(4/3\pi c^3)^{1/2} \qquad (6)$$

This demonstrates a square root spherical structure. From here we may deduce the most logical internal structure of the quasi electron as derived from quintessence. Indeed if the quasi electron has a square root spherical structure, this needs to be accounted for when calculating the number of quintessence it contains to account for the square root sphere conformation of the electron.

The structure can be defined using the equation for the surface area of a sphere: $A=4\pi r^2$. Thus the total volume of a single outer layer of quintessence in the quasi electron will be the surface area of the quasi electron x the average diameter of quintessence [if quintessence is oscillating the average diameter is $(2r_q + 0)/2 = r_q$].

Taking r_e as the radius of the electron and r_q as the radius of quintessence, given that there are three quasi electrons in the total electron, the volume of a single outer layer of quintessence (V) is:

$$V = (4\pi r_e^2)^{1/2} x \ (r_q/3)^{1/2}$$

Taking the volume of a single quintessence (V_q); based on a square root electron sphere, then:

$$V_q = (4/3\pi r_q^3)^{1/2}$$

The total number of quintessences in a single outer layer will thus be the total volume divided by the volume of a single quintessence itself: V/V_q. Thus the number of quintessences (n_q) in a single outer layer is:

$$n_q = (4\pi r_{qe}^2)^{1/2} x \ (r_q/3(4/3\pi r_q^3)^{1/2}$$

This very elegantly reduces to

$$n_q = r_e/r_q$$

To be further precise (after all quantum dynamics has to be elegant), the total number of quintessences in the electron will thus be determined by the number of quintessences in a single outer electron layer x the quantum amplitude. The quantum amplitude has been previously calculated using the standard Shrödinger wave equation (see Fundamental Forces and Particle Physics) and is given by $(c^{1/2}/\pi)$. Taking the root mean square of the quantum amplitude, the number of quintessences (n_q) in the electron is:

$$n_q = r_e/r_q \ x \ \sqrt{2}(c^{1/2}/\pi).$$

As the radius of the electron is estimated as, $r_e = 6.4 \times 10^{-19}$ m. (see Particle spin and Size), and the radius of quintessence is, $r_q = 1.35 \times 10^{-35}$ m, this allows us to estimate the number of quintessences in the electron itself using the above equation, thus:

$$\mathbf{n_q = 1.2355 \ x \ 10^{20} \ m}$$

Thus, given that m_q = 7.373 x 10^{-51} kg, the mass of the electron is given by

$$m_e = m_q \ x \ n_q, = 9.10938 \ x \ 10^{-31} \ kg.$$

Using the radius for quintessence (the estimated Planck length) then the number of quintessences present in the electron and thus its mass, is explained.

Therefore, these observations postulate that the internal structure of the electron consists of a square root sphere, composed of a single outer layer of quintessence x the root mean square of the its quantum amplitude.

The electron is itself composed of quintessence with a velocity of c and has an intrinsic radius of 1/c x 1/spin in metres; and in accordance with its half integer spin $h/4\pi$; its spin velocity is $2\pi/c$ in metres/sec, (see Particle Spin and Size) which in vortex mechanics gives it the ideal harmonic balance with quintessence space time.

Thus given the surface area of the quasi electron in order to fill the outer layer allowing for the quantum amplitude of oscillation would require 1.235×10^{20} quintessences. The total number of quintessence required to fill the whole electron would thus be $n_q = 1.235 \times 10^{20}$. Overall the number of quintessences required to make up the electron can be verified from the internal structure of the electron and the radius of quintessence. Thus if r_q is equivalent to the given Planck length, then accordingly the number of quintessences in the electron is calculated as 1.235×10^{20}, which gives the mass of the electron $m_e = m_q \times n_q$, hence again:

$$m_e = m_q \times n_q, = 9.10938 \times 10^{-31} \text{ kg}.$$

Intriguingly the derivation of the structure of the electron reflects the volume of an ordinary sphere

$$V = 4\pi r^2 \times r/3 = 4/3\pi r^3$$

This underpins a fundamental concept, mass determines the shape of space-time and in turn the shape determines the amount of mass within it.

It is important to have a working understanding of why the mass of the electron should be what it is from its basic structure. This understanding can now be derived from the radius of quintessence, which also corresponds with the Planck length.

Dimensional Equations for Quintessence

As $h = 3m_qc^2$ and the dimensions of h are $[ML^2T^{-2}.T]$ and those of c^2 are $[L^2.T^{-2}]$ the equational dimensions of quintessence are [M][T], and the dimensions relating to the number of quintessences n_q is $[T^{-1}]$. Clearly therefore,

$$[M] = [M][T] \times [T^{-1}]$$

and overall

$$M = m_q \times n_q.$$

Dimensional Equations for the Electron

The dimensions of the equation for the electron, in the light of quintessence, can now be fully examined, if

$$e^2 = \frac{\varepsilon o}{3\ (4/3\pi c^3)} \qquad (6b)$$

Then taking the dimensions of the equation, e^2 is the charge $[q^2]$, in Coulombs; ε_0 is the permittivity of free space, in Capacitance [C] per metre [L]; and [c] is the speed of light, in [L/T].

Thus the above equation using dimensions, is given by

$$[q^2] = \frac{[C]}{[L][c^3]}$$

In this case the velocity is given as the velocity of light c, then L = c.T ; then

$$[q^2] = \frac{[C]}{[c^4][T]}$$

As $q^2 = C^2V^2$, where V is volts, then:

$$[C^2][V^2] = \frac{[C]}{[c^4][T]}$$

and

$$[CV^2] = \frac{1}{[c^4][T]}$$

as $E = CV^2$, then

$$E = \frac{1}{[c^4][T]}$$

and as $E = mc^2$, then

$$mc^2 = \frac{1}{[c^4][T]}$$

and hence

$$m = \frac{1}{[c^6][T]}$$

The significance of this dimensional analysis, in the first instance, appears obscure. Nevertheless, it reveals the very nature of matter and energy. Thus the equation for the mass of a structure can be represented by **$1/c^6$ which represents the six complex vectors of matter.**

Interestingly, given it is known that $1/c^2 = [\mu_o.\varepsilon_0]$, then

$$m = [\mu_o.\varepsilon_0]^3/T$$

Where μ_o. and ε_0 are again the permeability and permittivity of free space, quantities that are inherently caused by the vibration of quintessence. Thus mass itself is the result of the vibration of quintessence in the six complex vectors (each represented by the fundamental properties of quintessence μ_o or ε_0 .Hence, the equation for the quasi electron mathematically and geometrically forms the "perfect" three dimensional sphere with its mass accounted for by its six complex vectors.

Energy associated with this matter is in turn is also caused by the the vibration of quintessence (including that in the complex vectors, i) such that:

$$E = [\mu_o.\varepsilon_0]^2/T$$

The dimensions for the equation for energy can also be written as:

$$E = \frac{1}{c^3.L}$$

Which indicates that the energy of matter is again related to the dimensions of the structure of the electron $\varepsilon_0 /(4/3\pi c^3)$ and the permittivity of free space in capacitance per meter (C/L)

Overall the equation for the quasi electron and its dimensions, gives us the origin of mass and energy. The equation for the electron then forms the key to the understanding of the nature of the relationship between matter and space-time.

Indeed we may now even derive Newton's second law of motion (F = ma, and thus the other fundamental laws of physics) from first principles to confirm the validity of the above.

If:

$$E = \frac{1}{[c^4.][T]}$$

Which is dimensionally equivalent to:

$$E = \frac{[T^3]}{[L^4]}$$

then as F = E/L:

$$F = \frac{[T^3]}{[L^5]}$$

and thus

$$F = \frac{[T^6]}{[L^6.T]} \cdot \frac{[L]}{[T^2]}$$

Substituting for m from eq. 1g

$$m = \frac{[T^6]}{[L^6][T]}$$

Then $F = ma$

Thus taking into account the whole of these observations enables the laws of motion and the equations for energy and mass and their equivalence to be derived from geometric first principles.

UNITED STATES PATENT OFFICE.

EDWIN H. ARMSTRONG, OF YONKERS, NEW YORK,

WIRELESS RECEIVING SYSTEM.

1,113,149. Specification of Letters Patent. Patented Oct. 6, 1914.

Application filed October 29, 1913. Serial No. 797,947.

To all whom it may concern:

Be it known that I, Edwin H. Armstrong, a citizen of the United States, residing at 1032 Warburton avenue, Yonkers, county of Westchester, State of New York, have invented certain new and useful Improvements in Wireless Receiving Systems; and I do hereby declare the following to be a full, clear, and exact description of the invention, such as will enable others skilled in the art to which it appertains to make and use the same.

The present invention relates to improvements in the arrangement and connections of electrical apparatus at the receiving station of a wireless system, and particularly a system of this kind in which a so-called "audion" is used as the Hertzian wave detector; the object being to amplify the effect of the received waves upon the current in the telephone or other receiving circuit, to increase the loudness and definition of the sounds in the telephone or other receiver, whereby more reliable communication may be established, or a greater distance of transmission becomes possible. To this end I have modified and improved upon the arrangement of the receiving circuits in a manner which will appear fully from the following description taken in connection with the accompanying drawings. As a preliminary, it is to be noted that my improved arrangement corresponds with the ordinary arrangement of circuits in connection with an audion detector to the extent that it comprises two interlinked circuits; a tuned receiving circuit in which the audion grid is included, and which will be hereinafter referred to as the "tuned grid circuit", and a circuit including a battery or other source of direct current and the "wing" of the audion, and which will be hereinafter referred to as the "wing circuit". As is usual, the two circuits are interlinked by connecting the hot filament of the audion to the point of junction of the tuned grid circuit and the wing circuit. I depart, however, from the customary arrangement of these circuits in a manner which may, for convenience of description, be classified by analysis under three heads; firstly, the provision of means, or the arrangement of the apparatus, to impart resonance to the wing circuit so that it is capable of sustaining oscillations corresponding to the oscillations in the tuned grid circuit; secondly, the provision of means supplementing the electrostatic coupling of the audion to facilitate the transfer of energy from the wing circuit to the grid circuit, thereby reinforcing the high frequency oscillations in the grid circuit, and thirdly, the introduction into the wing circuit of an inductance through which the direct current of the wing circuit flows, and which is so related to the grid circuit that the maintaining electromotive-force across the terminals of the inductance due to reduction of the direct current, is effective in the tuned grid circuit to increase the grid charge and consequently to further reduce the current in the wing circuit and in the telephones. By a further extension of this idea, the effect of the maintaining electromotive-force upon the grid current may be augmented by the use of a transformer in a manner which will be understood from the following description.

Figure 1 illustrates the arrangement and connection of apparatus with which I have thus far obtained the best results and which embodies in combination the several features of improvement which I have invented or discovered. Fig. 2 represents a like arrangement with the exception that there is no transformer for augmenting the effect of the maintaining electromotive-force, and several condensers, which may advantageously be employed but which are not essential, are eliminated. Fig. 3 illustrates an arrangement in which the advantages of my invention are only partially present, the inductance which produces the maintaining electromotive-force effective on the tuned grid circuit being eliminated. Fig. 4 illustrates an arrangement in which inductance, in this case the inductance of the telephones, is employed for producing the maintaining electromotive force effective on the tuned grid circuit, but the wing circuit is not resonant. Fig. 5 illustrates an arrangement in which an inductance replaces the telephones in that portion of the connections which is common to the two circuits, and the telephones are put in the wing circuit, and Fig. 6 illustrates an arrangement in which a double winding transformer is used, the primary being located in the wing circuit.

Referring particularly to Fig. 1, A represents the ordinary grounded aerial connected to the primary P of an oscillation transformer, the secondary S of which is connected as usual in the tuned grid circuit, this circuit also including the inductance L and preferably a shunted capacity C as is usual. Between the inductance L and the audion grid G is located a condenser C' adapted to receive and hold the charge which accumulates on the grid as a result of the received oscillations. The grid lies within the audion in the path of current in the wing circuit and the grid circuit is connected to the wing circuit at the junction point O, so that the two circuits are interlinked from the grid to that point. Between the junction point O and the filament of the audion I insert the telephone receivers R and the primary of the auto-transformer T. From junction point O the tuned grid circuit is completed through the secondary of the auto-transformer and condenser C^2 back to the secondary S; and the condenser C^5 is connected as shown in shunt to the telephones and the secondary of the auto-transformer. The wing circuit may be traced from the positive terminal of the battery through the inductance L' to the wing W and through the connections which are common to the two circuits, including the current path through the audion to the filament F, the telephone receivers R, and the primary of the auto-transformer and back to the negative terminal of the battery. The inductance L' is preferably shunted by a condenser C^3 and a condenser C^4 is placed across the battery terminals to afford a path of low impedance for the high frequency oscillation. The telephones R and the auto-transformer T are shunted by a condenser C^5, which affords a path for the high frequency oscillations in the grid circuit; and the telephones R and the primary of the auto-transformer are shunted by a capacity C^6, which affords a path for the high frequency oscillations in the wing circuit, and I find that the audion is made more stable and shows less tendency to become a high frequency generator and to set up oscillations in the interlinked circuits, if the tuned grid circuit is grounded as indicated. Each of the pieces of apparatus crossed with an arrow on the drawing is continuously variable, that is, may be varied by infinitesimal increments, and the condenser C^4 is preferably made adjustable by steps. I find that with such an arrangement of apparatus, and by properly adjusting the reactances, signals which are scarcely audible with the ordinary audion connection can be amplified to a point where they are too strong for, and "paralyze" the most stable audions that I have been able to obtain. The present understanding and modes of explanation of the phenomena which present themselves in such an arrangement is such that any theory of operation which may be advanced in regard to them is merely an attempt to explain the results attained in language which will be understandable to those skilled in the art; and it is with this idea in mind that the following description is written.

Upon reference to Fig. 2 of the drawings, which is an attempt to simplify the illustration of the essential elements of my invention, it will be observed that the auto-transformer T, and the condensers C^2, C^3, C^5, and C^6, are omitted. In this case the capacity of the telephone cords is sufficient to by-pass the high frequency oscillations.

The effect of tuning the wing circuit to the received high frequency oscillations by such an arrangement of apparatus as is illustrated in Fig. 3, may be explained as follows: In the ordinary audion connection, the wing W will be constantly maintained at the same potential with respect to the filament F and will constitute a surface of positive potential within the audion and having a constant tendency to absorb electrons. When the wing circuit is made resonant in accordance with my invention, the initial received oscillations in the grid circuit set up corresponding oscillations in the wing circuit so that a negative charge on the grid is accompanied by an increase of the potential of the wing, and a positive charge on the grid is accompanied by a decrease of the potential of the wing. The absorption of electrons by the grid and the building up of the charge in the condenser C' occurs only when the potential of the grid is positive with respect to the potential of the filament, and during these periods the potential of the wing with respect to the filament is reduced, thereby reducing its absorption of electrons and increasing the absorption of electrons by the grid. The charge thus built up in the condenser C' by absorption at the grid is entrapped and is an effective counter-electromotive-force in the wing circuit to reduce the current in the telephones. It is understood that on each successive wave train this effect is repeated, it being probable, according to my observations, that the full condenser charge is not built up by the first wave of a train but is gradually built up during the first portion of the wave train; and because of the high resistance of the discharge path of the condenser C′, this charge outlasts the duration of the wave train.

Referring now to Fig. 4, we may examine the effect of an inductance inserted in the wing circuit and related to the grid circuit as above defined. The reduction of current through the telephones, due to the received oscillations, produces a maintaining electromotive-force across the terminals of the telephones R which is in the same direction as the battery electromotive-force, and, because of the fact that the telephones are in that portion of the connections which is common to the two circuits, this maintaining electromotive-force is effective upon the tuned grid circuit to charge the condenser C′ in the same sense that the flow of electrons from the filament to the grid would charge the condenser. I have found, as a practical matter, that the arrangement of apparatus shown in Fig. 4 is effective to materially increase the loudness of the signals, but obviously better effects are obtained by combining the arrangements of Figs. 3 and 4 to make up the arrangement of Fig. 2. In this figure an auto-transformer L. is used instead of the two-coil transformer P. S., and in Figs. 2 and 4 the capacity of the telephone cords affords a path of low impedance for the passage of the high frequency oscillations about the inductance of the telephones. It will be observed, that this capacity of the telephone cords in Figs. 2 and 4, and likewise the capacity C^5 in Fig. 5 and the distributed capacity of the transformers in Figs. 1 and 6, is in each case common to the grid circuit and the wing circuit and constitutes an electrostatic coupling facilitating the transfer of energy from the wing circuit to the grid circuit and increasing the effect upon the grid of high frequency pulsations in the wing circuit. This effect occurs whether the wing circuit is tuned or not, but obviously the transfer of energy is increased by tuning the two circuits alike. I have discovered, however, that the beneficial effect may be still further increased by the interposition of a transformer in such a way as to increase the effect of the maintaining electromotive-force due to the reduction of current through the telephone receivers, and such a transformer is shown at T in Fig. 1. With the foregoing discussion in mind the effect of this transformer will at once be apparent. The inductance of the primary of the transformer is of course added to and increases the effect of the inductance of the telephones, but beyond this the maintaining electromotive-force across the primary is transformed into a higher electromotive-force in the tuned grid circuit. I have found that a ratio of transformation of 2 to 1 is sufficient in most cases when the inductance of the primary is equal to the inductance of the telephones, since a greater ratio causes the audion to become a high frequency generator setting up disturbing oscillations in the grid and wing circuits. The condenser C^5 by-passes the high frequency oscillations in the grid circuit about the telephones and the auto-transformer T, and the condenser C^6 by-passes the oscillations in the wing circuit about the telephones and the primary of the auto-transformer. The capacity of the telephone cords may, however, be relied upon to by-pass the oscillations about the telephones and condensers C^5 and C^6 utilized for by-passing the oscillations about the transformer only. The manner in which the different reactances will be adjusted so as to tune the two circuits to one another will be at once understood by those skilled in the art, and it will also be understood that the adjustable resistance X may be varied to get the proper temperature of the filament. Furthermore, it will be understood from what has been said that the ratio of transformation of the transformer should be adjusted to get the maximum signals without causing the audion to generate oscillations. The condenser C^5 has the additional effect, as I have found, to steady the audion and enable it to withstand greater variations of potential of the grid G and wing W without becoming a generator of disturbing oscillations in the grid and wing circuits. Particularly when working with long waves it is advisable to use this condenser in every case. I also find that the introduction of a condenser C^2 in the place indicated in Fig. 1, that is, between the auto-transformer and the secondary S, has the effect to prevent buzzing or humming in the telephones.

From what has been said, it will be understood that the inductance of the telephones may be utilized as the generator of the maintaining electromotive-force by inserting the telephones in the connections common to the two circuits, as shown in Figs. 1, 2 and 4; but a like result will be obtained by locating the telephones in the wing circuit as indicated in Fig. 5, and placing a suitable inductance as L^2 in that portion of the connections which is common to the two circuits. Indeed I find that the beneficial effect of an inductance so located can be obtained, as would be expected, by utilizing the primary of the transformer alone, as indicated in Fig. 6. In this case a two coil transformer is shown in place of an auto-transformer and the variations of current in the primary induce potential variations in the secondary which may be given any value by properly selecting the ratio of transformation.

Inasmuch as the purpose of the transformer is to magnify the effect of the maintaining electromotive-force in the inductance, it will be obvious that by increasing this inductance, the transformer may be rendered unnecessary, and some simplification of the whole arrangement may be attained by using telephone receivers of extremely high inductance and locating them in the position shown in Fig. 2, without any transformer.

The purpose of the condenser C^3 in Fig. 1 is to enable the wing circuit to be made resonant with the grid circuit when long waves are to be received. The capacity of the audion and the distributed capacity of the inductance L' are such that up to 2000 meters wave length resonance can be obtained in the wing circuit with reasonable values of inductance. For waves longer than 2000 meters resonance can be obtained in the wing circuit without the parallel condenser, but only by unduly increasing L'.

For the purpose of completing the disclosure of my invention, and to facilitate its practical application by those skilled in the art, I give below the values of the constants which I have found to work well for a wave length of 1800 meters, using an antenna having a capacity of .0012 microfarads and a standard McCandless audion. The inductance of the primary P was 760 microhenries and the combined inductance of the secondary S and the coil L was 3660 microhenries. The capacity of C was about .00025 microfarads, the capacity of C^2, .01 microfarads, and of C^4, 2 microfarads. The values of C' and L' are largely dependent upon one another and upon the amplitude of the received oscillations as well as the characteristics of the audion. These are the two elements which are chiefly relied upon by the operator to bring the system into condition to give the best results in receiving the signals from any particular station. The value of L' will be in the neighborhood of 10,000 microhenries, and of C' between .00003 and .0001 microfarads. If the inductance L' is not used, the value of C' can be much larger. I have usually employed about .003 microfarads as a matter of convenience; but there does not seem to be any particular advantage in increasing the capacity of C' beyond .0005 microfarads. The batteries, and the resistance X, are as used in the standard audion set. The way to tune this set is to cut out L', set C' at .00005 microfarads, and then adjust P, S, L and C as in the ordinary audion set until signals are strongest. The inductance L' is then gradually cut in and the strength of the signals will increase many times until a point is reached where the signals lose distinctness and there is a loud hiss in the telephones. This indicates that the audion is generating high frequency oscillations in the grid and wing circuits, and the inductance L' should be set at a point just below that at which this occurs. If there is no hiss as L' is increased, and the signals pass through a maximum of strength and begin to fall off, then L' should be set at the point of maximum strength of signals and C' should be increased to a point just below that at which the hiss appears. Under these circumstances, the increase of C' will be accompanied by an increase of the strength of the signals, the maximum strength being obtained in each case just below that point at which the audion begins to act as a generator of high frequency oscillations.

I find that the capacity required to bypass the oscillations about the inductance which is common to the two circuits, and about the transformer, if the transformer is used, is relatively small; and when the telephone receivers are used as the inductance at this point, the capacity of the telephone cords is sufficient. With greater wave lengths, however, when it becomes necessary to increase the tuning inductances L and L', the audion begins to be unstable, and I find that its stability can be restored by the use of a considerably larger capacity C^5. For example, with wave lengths of 4000 to 7500 meters I use a capacity C^5 of from .001 to .003 microfarads.

Having thus described my invention, what I claim is:

1. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, the resonant grid circuit having a capacity so related to the grid as to receive and retain the charge which accumulates thereon.

2. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, the resonant grid circuit having a capacity so related to the grid as to receive and retain the charge which accumulates thereon, and an inductance through which the current in the wing circuit flows, the grid circuit including connections for making effective upon that circuit the potential variations resulting from a change of current in the wing circuit.

3. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, the resonant grid circuit having a capacity so related to the grid as to receive and retain the charge which accumulates thereon, and an inductance in that portion of the connections which is common to the two circuits.

4. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the

received oscillations are impressed, the resonant grid circuit having a capacity so related to the grid as to receive and retain the charge which accumulates thereon, an inductance in that portion of the connections which is common to the two circuits, and a transformer having its primary in the wing circuit and its secondary in the grid circuit.

5. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, the resonant grid circuit having a capacity so related to the grid as to receive and retain the charge which accumulates thereon, and a telephone receiver in that portion of the connections which is common to the two circuits.

6. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, the resonant grid circuit having a capacity so related to the grid as to receive and retain the charge which accumulates thereon, a telephone receiver in that portion of the connections which is common to the two circuits, and a transformer having its primary in the wing circuit and its secondary in the grid circuit.

7. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, the resonant grid circuit having a capacity so related to the grid as to receive and retain the charge which accumulates thereon, an inductance in that portion of the connections which is common to the two circuits a transformer having its primary in the wing circuit and its secondary in the grid circuit, and condensers affording paths of low impedance about the inductance and transformer for the high frequency oscillations in both circuits.

8. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, and an inductance in that portion of the connections which is common to the two circuits.

9. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, and an inductance through which the current in the wing circuit flows, the grid circuit including connections for making effective upon that circuit the potential variations resulting from a change of current in the wing circuit.

10. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit, an inductance in that portion of the connections which is common to the two circuits, and a transformer having its primary in the wing circuit and its secondary in the grid circuit.

11. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, an inductance in that portion of the connections which is common to the two circuits, a transformer having its primary in the wing circuit and its secondary in the grid circuit, and condensers affording paths of low impedance about the inductance and transformer for the high frequency oscillations in both circuits.

12. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, and a high inductance telephone receiver in that portion of the connections which is common to the two circuits.

13. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, a capacity between that portion of the grid circuit upon which the oscillations are impressed and the grid, and a second capacity between the point of junction of the grid circuit with the wing circuit and that portion of the grid circuit upon which the oscillations are impressed.

14. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, an inductance in that portion of the connections which is common to the two circuits, and a stabilizing capacity shunted about said inductance.

15. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, and means supplementing the coupling of the audion to facilitate transfer of energy from the wing circuit to the grid circuit, whereby the effect upon the grid of high frequency pulsations in the wing circuit is increased.

16. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which the received oscillations are impressed, and means supplementing the coupling of the audion to facilitate transfer of energy from the wing circuit to the grid circuit, whereby the effect upon the grid of high frequency pulsations in the wing circuit is increased.

17. An audion wireless receiving system having a wing circuit interlinked with a resonant grid circuit upon which received

oscillations are impressed and an electrostatic coupling between the circuits supplementing the coupling of the audion to facilitate transfer of energy from the wing circuit to the grid circuit, whereby the effect upon the grid of high frequency pulsations in the wing circuit is increased.

18. An audion wireless receiving system having a resonant wing circuit interlinked with a resonant grid circuit upon which received oscillations are impressed and an electrostatic coupling between the circuits supplementing the coupling of the audion to facilitate transfer of energy from the wing circuit to the grid circuit, whereby the effect upon the grid of high frequency pulsations in the wing circuit is increased.

In testimony whereof I affix my signature, in presence of two witnesses.

The Research of Dr. Hulda Regehr Clark, Ph. D., N.D.

I have recently (9/15/2000) come across the research of Dr. Hulda Regehr Clark, Ph. D., N.D. In her books, she states that many diseases, among which are cancer and HIV/AIDS, can be cured by the use of, among other things, certain herbs and a frequency generator called a "Zapper" that was invented by her and her son.

Speaking of mothers :), my mother, 62, had fatigue and arthritic symptoms in her hands before I found out about and told her about Dr. Hulda Clark. She is a seamstress, so the arthritic symptoms hindered her work. After doing the Parasite Cleanses and using the Zapper, she doesn't have to take naps like before and her hands are flexible again. She has done the complete Parasite Cleanse only twice but she Zaps practically every day.

Simple Zapper Information

Schematic updated on 12/21/2001

Simple Zapper Information text updated on 12/21/2001.

I forgot to mention that the Simple Zapper that I'm using has a 1 Megohm potentiometer instead of the 2.2k ohm resistor in order to vary the output frequency. If you use a potentiometer with the circuit put it in series with the 2.2k ohm resistor because the chip gets hot when there is too little resistance.

The duty-cycle is pretty consistent with a range of 51% to 57%. With the oscilloscope's frequency analyzer in storage mode, I hold the Zapper probes and put the oscilloscope probes somewhere on my body and then I vary the frequency of the Zapper using the 1 Megohm potentiometer.

When testing my body on a spectrum analyzer while using the Simple Zapper with an output of around 5 Volts (tested on a DC voltmeter), I noticed that the frequencies around 4,000 hz to around 18,000 hz had larger peaks telling me that my body at the time was more conductive (less reactive?) and/or less resistive to frequencies in this range at the given voltage.

With my body being more conductive (less reactive?) at these frequencies, I believe that there is a better dispersal of the Simple Zapper's output within my body. I did this recent test with one Zapper probe in each hand (as opposed to both in one hand) and the oscilloscope probes (RCA to 1/4" phone plug adaptor) in my mouth near my wisdom teeth with my lips around the RCA ground (like a lollipop).

The oscilloscope's frequency analyzer was in storage mode. With the Simple Zapper circuit on this page, change the 2.2k ohm resistor to 4.3k ohm if you want a ~15,000 hz frequency. I have recently built a couple of Zappers with optimized output frequencies of around 11,000 hz. I haven't tested anyone using the Simple Zapper other than myself, so there is the possibility that your body's response may differ.

For more information, check out my Simple Zapper webpage at:

www.members.aol.com/mas1911/index.html

or for really interesting free circuit schematics:

You can write the Author of Simple Zapper if you have comments or questions.

The following document, written by Luke Parrish, provides instructions on building an astable multivibrator in DC pulse mode, identical in output to the Zapper, described in The Cure For All Diseases by Dr. Hulda Clark.

Plans For Zapper

This page tells how to make a Hulda Clark-style "Parasite Zapper". It's a simpler and more efficient version, but works just as well. We make no theraputic claims for this device. It is for experimental purposes only. We provide a ready made version for those who prefer not to spend so much time building it.

Materials

- A CD4069 hex inverter (Radio Shack link)
- 1 1M resistor, 1 10k resistor, and 1 1k resistor (Radio Shack link) (Resistor color code)
- 1 1000 pF capacitor (Radio Shack link)

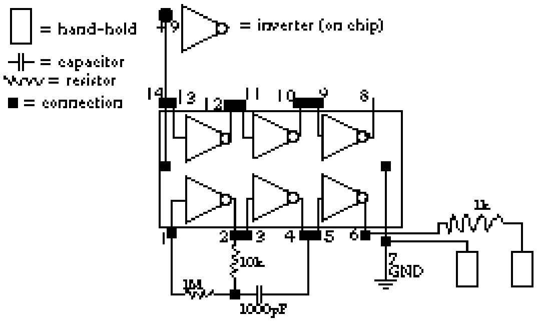
NOTE: The size of the resistors and capacitors can vary, because they determine the frequency of the zapper, which doesn't really matter much according to Hulda Clark.

The following parts may be substituted according to preference, though something similar will be needed:
- Solderless breadboard (Radio Shack link)
- 9-volt battery
- 4 alligator clip-leads sets Radio Shack link
- 2 copper pipes (hand-holds)

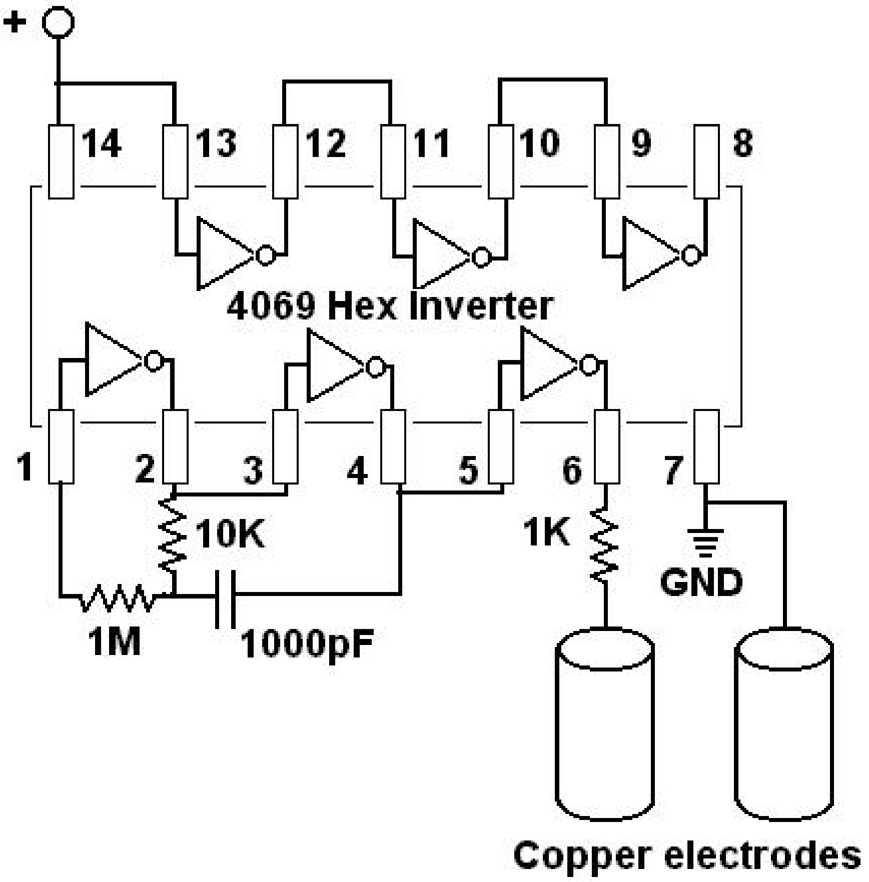
Instructions

Plug the components into the solderless breadboard according to the following schematic. Make sure none of the wires touch each other. To hook up the power, attach an alligator clip-lead to each side of the capacitor that stretches from hot to ground. Clip the one that goes to hot to the positive terminal on the battery and the one that goes to ground to the negative terminal. The two hand-holds are attached with the other two clip-leads. (One goes to ground, the other to the end of a resistor that goes to pin 12.)

Schematic



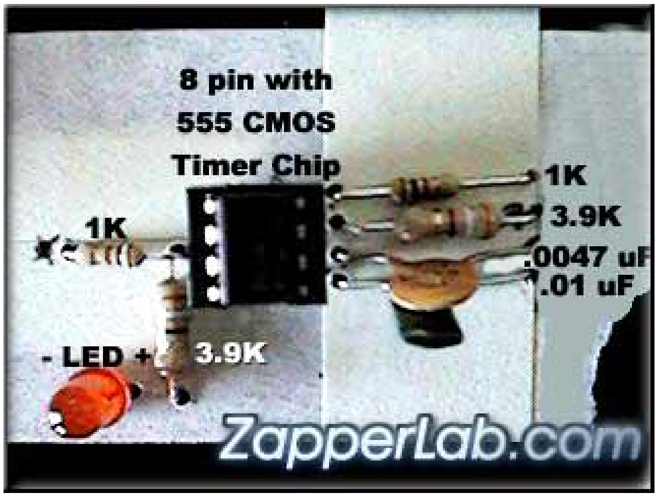
Schematic most recently updated 5-17-2001



The above instructions are not the only way to do it. You can, for example, solder all the components directly to a 14-pin socket, like we do in our ready made version. This is a lot more trouble and more time-consuming for most people, which is why we recommend a breadboard. The resistors and capacitor don't all have to be the exact sizes mentioned here to make a working Zapper. However, any variation in capacitance or resistivity will change the frequency. (There are certain limits on how high of frequencies the chip can handle, so don't stray too far from the specified values.) If you have an oscilliscope, that's handy to check if it's working.

Ready made Zappers

Free plans from Zapperlab.com



Here we have the easy step-by-step instructions for building your very own Hulda Clark Zapper reprinted with permission from her books (provided below). For advanced electricians there is a schematic for building a Hulda Clark Zapper as well. If you do not know anyone that could put one together for you, you can now order the zapper Hulda Clark uses as described in "The Cure For All Cancers" and "The Cure For All Diseases" at: www.SyncroZap.com. The Dr. Clark Zapper can be sold only as an experimental device, and no claim can be made by us legally as to a diagnosis, cure or treatment for any medical condition or disease.

Get from any Hardware Store:

2 Bolts 1/8" diameter, 2" long with 4 nuts and washers.

2 pieces of ¾" copper pipe, cut to 4 inches long each.

Editor's Note:

Remove 8 Pins From A 16 Pin Wire Wrap Socket

The **8 pin wire-wrapping socket** has been discontinued at many Radio Shacks and readers have asked what to do. Some say it is still available on their website at www.RadioShack.com, if not:

There are a couple options. One can still get the **16 pin wire-**

wrapping socket. Pull out the bottom grouping of 8 pins, and you now have an 8 pin socket. Just make sure when you plug the 555 Timer into it, you line it up with the remaining 8 pins. Very simple.

There is also a **Low Profile 8 pin socket**. The pins are so small one must solder to them.

The wire-wrap socket has long pins for easy twisting onto other wires. The low profile is for those that solder electronics.

If you are soldering your zapper together get the low profile 8 pin socket. Since the socket is just a saddle for the 555 Timer, it is not a vital part of the circuit. It's just a way to put long or short pins on the 555 Timer for easy twisting. If you cannot find one at your local Radio Shack, simply get the 16 pin wire-wrap socket, and pull out 8 pins. -editor.

Assembling The Zapper

If you have tools such as a drill, needle nose pliers, and small drill bits, buy one of the plastic project boxes on the list, otherwise build your zapper in a shoe box, or a box half the size of a shoe box.

1. You will be using the lid of the shoe box or plastic lid of the project box to mount the components. Save the box to enclose the finished project.

2. Pierce two holes near the ends of the lid. Enlarge the holes with a pen or pencil until the bolts would fit through. Mount the bolts on the outside about half way through the holes so there is a washer and nut holding it in place on both sides. Tighten. Label one hole "grounding bolt" on the inside and outside.

3. Mount the 555 chip in the wire wrap socket. Find the "top end" of the chip by searching the outside surface carefully for a cookie-shaped bite or hole taken out of it. Align the chip with the socket and very gently squeeze the pins of the chip into the socket until they click in place.

4. Make 8 pinholes to fit the wire wrap socket. Enlarge them slightly with a sharp pencil. Mount it on the outside. Write in the numbers of the pins (connections) on both the outside and inside, starting with number one to the left of the "cookie bite" as seen from outside. After number 4, cross over to number 5 and continue. Number 8 will be across from number 1. The pins are numbered like this:

1	8
2	7

3 6

4 5

5. Pierce two holes ½ inch apart very near to pins 5,6,7, and 8. They should be less than 1/8 inch away. (Or, one end of each component can share a hole with the 555 chip.) Mount the .01 uF capacitor near pin 5 on the outside. On the inside connect pin 5 to one end of this capacitor by simply twisting them together. Loop the capacitor wire around the pin first; then twist with the long-nose pliers until you have made a tight connection. Bend the other wire from the capacitor flat against the inside of the shoe box lid. Label it .01 on the outside and inside. Mount the .0047 uF capacitor near pin 6. On the inside twist the capacitor wire around the pin. Flatten the wire from the other end and label it .0047. Mount the 3.9 K Ohm resistor near pin 7, connecting it on the inside to the pin. Flatten the wire on the other end and label it 3.9. Mount the 1 K Ohm resistor and connect it similarly to pin 8 and label it 1K.

6. Pierce two holes ½ inch apart next to pin 3 (again, you can share the hole for pin 3 if you wish), in the direction of the bolt. Mount the other 1 K Ohm resistor and label inside and outside. Twist the connections together and flatten the remaining wire. This resistor protects the circuit if you should accidentally short the terminals. Mount the 3.9 K Ohm resistor downward. One end can go in the same hole as the 1K resistor near pin 3. Twist that end around pin 3 which already has the 1K resistor attached to it. Flatten the far end. Label.

7. Next to the 3.9 K Ohm resistor pierce two holes ¼ inch apart for the LED. Notice that the LED has a positive and a negative connection. The longer wire is the positive (anode). Mount the LED on the outside and bend back the wires, labeling them + and - on the inside.

8. Near the top pierce a hole for the toggle switch. Enlarge it until the shaft fits through from the inside. Remove nut and washer from switch before mounting. You may need to trim away some paper with a serrated knife before replacing washer and nut on the outside. Tighten.

9. Next to the switch pierce two holes for the wires from the battery holder and poke them through. Attach the battery and tape it to the outside.

Now To Connect Everything

Twist free ends of the two capacitors .01 and .0047 together. Connect to Grounding Bolt using an alligator clip.

Bend pin 2 and pin 6 together inward, using an alligator clip, catch them and connect to free end of 3.9K Ohm (by pin 7).

Alligator clip Pin 7 to free end 1K Ohm (near pin 8)

Using two microclips Pin 8 and pin 4 to one end of switch (use hole to attach both microclips).

Free end of 1K Ohm (by pin 3) to the Bolt using an alligator clip.

Alligator clip the free end of 3.9K Ohm (by pin 3) to plus end (long) of LED.

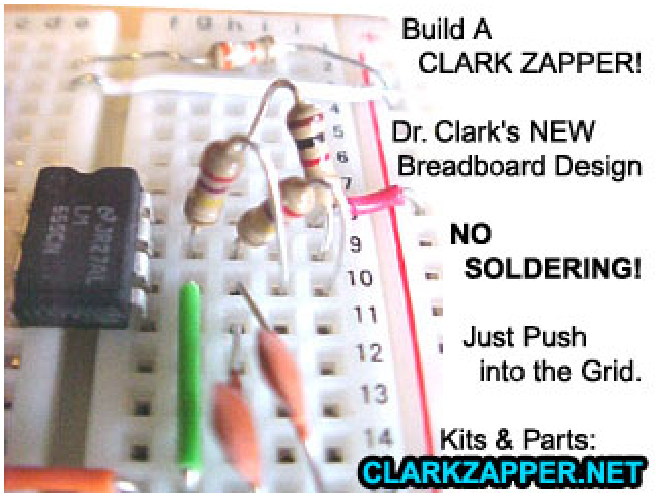
Minus end (short) of LED to Grounding Bolt with an alligator clip.

Alligator clip pin 1 to the Grounding Bolt.

Alligator clip Black battery wire to Grounding Bolt.

Micro clip the Red battery wire to free end of switch.

Hook up the battery, and the light should turn on, click the switch if it does not, check connections if LED does not light up.



Attach a long lead wire to the grounding bolt & bolt, and then to the copper handles. Wrap handles in paper towel, clip with lead wire, wet handle when you are ready to zap.)

How To Zap

Wrap handles in wet paper towel, or wet cotton sleeves, and hold in each hand. If you have wrist cuffs, run them under water to wet them, attach to each wrist.

Attach handles or wrist cuffs to zapper.

Turn zapper on, zapping for 7 minutes.

At end of 7 minute zapping rest 20 minutes.

Do this a minimum of three 7 minute zapping sessions, with a 20 minute break in between each session. Some people zap five times in extreme cases.

(57) **ABSTRACT**

An energy conversion system for extracting energy from the zero-point field of space is disclosed and described. This system includes a primary transducer operatively associated with a secondary transducer. The primary transducer can include a substrate having an arm rotatably coupled to the substrate, while the substrate can be confined to move along a linear oscillatory path. The secondary transducer converts kinetic energy of the substrate and arm to usable energy. The multi-mode motion of the substrate and arm combination is sufficient to impart a momentum influx to rotational motion of the arm.

The momentum influx can then be converted to usable energy such as mechanical, electrical and/or thermal energy. As described in more detail herein, the momentum influx appears to be a result of radiation pressure due to scattering in part of the electro-magnetic momentum-energy contained within the zero-point field of space opposite to centripetal acceleration of the arm.

ZERO POINT ENERGY ROTATOR TRANSDUCER AND ASSOCIATED METHODS

RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Application No. 61/088,913, filed Aug. 14, 2008 which is incorporated herein by reference.

FIELD OF THE INVENTION

[0002] This invention relates to generation of energy from the zero-point energy field of space or electromagnetic quantum vacuum. More specifically, the invention relates to a device useful for extraction of useful work via a sliding rotator. Therefore, the present invention relates generally to the fields of physics, quantum physics, and electromagnetism.

BACKGROUND OF THE INVENTION

[0003] The now ubiquitous drive for energy independence has provided a new set of incentives and appreciation for development of environmentally and economically responsible energy resources. Conventional discussions regarding such energy resources often revolve around fossil fuels, nuclear, and "alternative energy sources" such as solar, wind, bio fuels, hydrogen, fuel cells, and the like. Each of these energy resources currently comes with various benefits and drawbacks and often entail trade-offs between perceived pollution and environmental problems, costs, efficiencies, and unintended consequences (e.g. corn demand for use as fuel versus food).

[0004] Since at least the 1960's some theoretical physicists have proposed the concept of zero-point energy which suggests a background energy field throughout space. Historically, these physicists have been at least partially marginalized by mainstream academic thought. However, over the past decade or so, such theories have begun to gain significant traction in terms of recognition and available proofs to support these theories. Although this developing area of physics has experienced progress, practical applications of such theories remain severely limited. One example of such progress in practical applications is the work of Bernard Haisch and others in capitalizing on the Casimir effect. Such efforts thus far remain relegated to the quantum level. Although a wide variety of purported devices and claims have been made, no macroscale efforts have yet proven to yield useful energy gains.

SUMMARY OF THE INVENTION

[0005] In light of the relative infancy of the field and deficiencies noted above, the present invention provides an energy conversion system for extracting energy from the zero-point field of space. This system includes a primary transducer operatively associated with a secondary transducer. The primary transducer can include a substrate having an arm rotatably coupled to the substrate, while the substrate can be confined to move along a linear oscillatory path. The secondary transducer converts kinetic energy of the substrate and arm to usable energy. The multi-mode motion of the substrate and arm combination is sufficient to impart a momentum influx to a rotational motion of the arm. The momentum influx can then be converted to usable energy such as mechanical, electrical and/or thermal energy. As described in more detail herein, the momentum influx appears to be a result of radiation pressure resulting from scattering in part of the electro-magnetic momentum-energy contained within the zero-point field of space opposite to centripetal acceleration of the arm.

[0006] There has thus been outlined, rather broadly, the more important features of the invention so that the detailed description thereof that follows may be better understood, and so that the present contribution to the art may be better appreciated. Other features of the present invention will become clearer from the following detailed description of the invention, taken with the accompanying drawings and claims, or may be learned by the practice of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0007] The present invention will become more fully apparent from the following description and appended claims, taken in conjunction with the accompanying drawings. Understanding that these drawings merely depict exemplary embodiments of the present invention and they are, therefore, not to be considered limiting of its scope. It will be readily appreciated that the components of the present invention, as generally described and illustrated in the figures herein, could be arranged, sized, and designed in a wide variety of different configurations. In particular, relative dimensions may vary and are generally not presented in an optimized configuration but are rather provided for clarity and convenience in describing the invention generally. Nonetheless, the invention will be described and explained with additional specificity and detail through the use of the accompanying drawings in which:

[0008] FIG. **1** is a schematic of an energy conversion system in accordance with one embodiment of the present invention.

[0009] FIG. **2** is a schematic of an energy conversion system having two rotating arms, one rotating clockwise and the other counterclockwise, in accordance with another embodiment of the present invention.

[0010] FIG. **3** is a schematic of an energy conversion system illustrating an electro-magnetic mechanism for accelerating the arm in accordance with yet another embodiment of the present invention.

DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

[0011] The following detailed description of exemplary embodiments of the invention makes reference to the accompanying drawings, which form a part hereof and in which are shown, by way of illustration, exemplary embodiments in which the invention may be practiced. While these exemplary embodiments are described in sufficient detail to enable those skilled in the art to practice the invention, it should be understood that other embodiments may be realized and that various changes to the invention may be made without departing from the spirit and scope of the present invention. Thus, the following more detailed description of the embodiments of the present invention is not intended to limit the scope of the invention, as claimed, but is presented for purposes of illustration only and not limitation to describe the features and characteristics of the present invention, to set forth the best mode of operation of the invention, and to sufficiently enable one skilled in the art to practice the invention. Accordingly, the scope of the present invention is to be defined solely by the appended claims.

[0012] The following detailed description and exemplary embodiments of the invention will be best understood by reference to the accompanying drawings, wherein the elements and features of the invention are designated by numerals throughout.

Definitions

[0013] In describing and claiming the present invention, the following terminology will be used.

[0014] The singular forms "a," "an," and "the" include plural referents unless the context clearly dictates otherwise. Thus, for example, reference to "an arm" includes reference to one or more of such members and reference to "converting" refers to one or more such steps.

[0015] As used herein with respect to an identified property or circumstance, "substantially" refers to a degree of deviation that is sufficiently small so as to not measurably detract from the identified property or circumstance. The exact degree of deviation allowable may in some cases depend on the specific context.

[0016] As used herein, "adjacent" refers to the proximity of two structures or elements. Particularly, elements that are identified as being "adjacent" may be either abutting or connected. Such elements may also be near or close to each other without necessarily contacting each other. The exact degree of proximity may in some cases depend on the specific context.

[0017] As used herein, a plurality of items, structural elements, compositional elements, and/or materials may be presented in a common list for convenience. However, these lists should be construed as though each member of the list is individually identified as a separate and unique member. Thus, no individual member of such list should be construed as a de facto equivalent of any other member of the same list solely based on their presentation in a common group without indications to the contrary.

[0018] Concentrations, amounts, and other numerical data may be presented herein in a range format. It is to be understood that such range format is used merely for convenience and brevity and should be interpreted flexibly to include not only the numerical values explicitly recited as the limits of the range, but also to include all the individual numerical values or sub-ranges encompassed within that range as if each numerical value and sub-range is explicitly recited. For example, a numerical range of about 1 to about 4.5 should be interpreted to include not only the explicitly recited limits of 1 to about 4.5, but also to include individual numerals such as 2, 3, 4, and sub-ranges such as 1 to 3, 2 to 4, etc. The same principle applies to ranges reciting only one numerical value, such as "less than about 4.5," which should be interpreted to include all of the above-recited values and ranges. Further, such an interpretation should apply regardless of the breadth of the range or the characteristic being described.

[0019] In the present disclosure, the term "preferably" or "preferred" is non-exclusive where it is intended to mean "preferably, but not limited to." Any steps recited in any method or process claims may be executed in any order and are not limited to the order presented in the claims. Means-plus-function or step-plus-function limitations will only be employed where for a specific claim limitation all of the following conditions are present in that limitation: a) "means for" or "step for" is expressly recited; and b) a corresponding function is expressly recited. The structure, material or acts that support the means-plus function are expressly recited in the description herein. Accordingly, the scope of the invention should be determined solely by the appended claims and their legal equivalents, rather than by the descriptions and examples given herein.

Embodiments of the Invention

[0020] Referring now to FIG. **1**, an energy conversion system **10** is shown generally for extracting energy from the zero-point field of space. The system can include a primary transducer **12** which is designed to extract energy from the zero-point field of space in the form of kinetic energy. Multi-mode motion can be induced in a primary transducer along an oscillatory path. The multi-mode motion can include a primary translational motion and a secondary motion such that abrupt changes in the primary translational motion are sufficient to impart a momentum influx to the secondary motion. In one embodiment, the primary transducer can include a substrate **14** having an arm **16** rotatably coupled to the substrate. The substrate is generally confined to move along an oscillatory path. A secondary transducer **20***a* can be operatively associated with the primary transducer to covert the momentum influx into usable energy. Thus, the systems of the present invention provide an energy conversion system for extracting energy from the zero-point field of space. Generally, the system includes a means for extracting momentum-energy from vacuum by the action of inertia and a means for converting the momentum-energy to usable energy operatively associated with the means for extracting momentum-energy.

[0021] More particularly, the substrate **14** can be any suitable member upon which a rotating arm **16** can be coupled or otherwise mounted. The substrate can be guided along the oscillatory path by any suitable mechanism such as, but not limited to, tracks, walls or the like. FIG. **1** shows a linear oscillatory path defined by a pair of tracks **18** along which the substrate can move. The substrate can move along the tracks via bearings, wheels, magnetically repulsive members, or any other suitable approach. Typically, it is most desirable to minimize friction between the substrate and tracks in order to maximize energy transfer to the secondary transducer. The substrate and arm can be formed of any suitable material which can be readily chosen based on designed parameters to meet various property requirements such as density, fracture strength, toughness, etc. Furthermore, the shape and contours of the substrate and arm can also be designed to minimize aerodynamic resistance due to the significant acceleration forces per unit of time experienced by the primary transducer.

[0022] In one aspect of the present invention, the substrate has a substrate mass (m_2) and the arm has an arm mass (m_1) such that a ratio of m_2 to m_1 is chosen to maximize a gain in kinetic energy (ΔKE) of the substrate. The rotating arm acts as the primary momentum influx extraction mechanism which experiences an inertial force acting opposite to the centripetal force acting on the rotating arm. A fraction of the inertial force is manifest at an axis of rotation which is rigidly attached to the substrate and which constrains the arm to rotate around this axis. The y-component of this force acting on the axis, denoted as the centrifugal reactive force, imparts an impulse on the substrate in the positive y-direction with respect to an x-y coordinate system when the arm rotates within the first quadrant of the said x-y coordinate system or imparts an impulse on the substrate in the negative y-direction when the arm rotates within the third quadrant of the said x-y coordinate system, such that the substrate experiences a net timerate influx of momentum from the zero-point energy field of space or an increase in the momentum of the substrate in either the positive or negative y-direction, depending on which quadrant the arm is rotating in.

[0023] The oscillatory path can be a linear track **18** which defined on both ends by a pair of resilient stationary members **20***a* and **20***b* oriented on either end of the linear track. During operation of the system, the primary transducer oscillates back and forth between the two stationary members. The approach at each end is accompanied by a transfer of kinetic energy of the primary transducer (e.g. substrate and arm) to the secondary transducer. The primary transducer can thus be coupled to the secondary transducer in a manner which allows for conversion of this kinetic energy to the secondary transducer. For example, this can be accomplished by providing an at least partially or substantially inelastic collision with the resilient stationary members. As discussed in more detail below, various mechanisms can be effectively used to convert kinetic energy of the primary transducer into usable energy, e.g. via mechanical, thermal, and/or electromagnetic features.

[0024] As can be readily appreciated, the arm and substrate need an initial input of energy from an external source to begin movement. The source of energy to initiate rotation of the arm can come from a conventional energy source, such as a battery. This external energy can be transferred to the arm such as by a coaxial motor, magnetic accelerator, external flywheel, or the like. For example, a drive motor can be operatively associated with the arm and configured to initiate rotational motion of the arm and sustain the rotational motion at a predetermined critical angular velocity. Another option is to provide a permanent magnet on the arm, e.g. at the free end, and a complimentary magnetic induction coil at a location external to the primary transducer. In this manner, an electric current applied to the induction coil creates a magnetic field sufficient to act on the permanent magnet and accelerate the arm. After a critical angular velocity is reached, the external source of energy (such as a battery, the power grid, etc.) for the motor or other suitable initiator mechanism can be switched to an alternative energy storage device such as collected energy.

[0025] Referring now to FIG. **2**, an alternative embodiment of the present invention is shown including an arm **22** and a secondary arm **24** each rotatably coupled to the substrate. In one embodiment, the secondary arm has an axis of rotation spaced apart from an axis of rotation of the arm **22**. Alternatively, the secondary arm could share a common axis of rotation. In either case, the secondary arm is coupled to the arm such that both the arm and the secondary arm rotate at a common angular velocity and opposite rotational directions. Typically, the secondary arm also has a substantially identical mass and dimensions to that of the arm. In other words, the arms swing forward and back in the same cycle, with common y-coordinates and mirror x-coordinates.

[0026] In one embodiment, a motor can drive the first arm, and the second arm can be driven by gears linked to the first arm, such that they are in sync with each other, rotating at the same angular speed but in opposite rotational directions. In such cases, the cosines of the rotation angle of each arm will always be equal in magnitude, but opposite in sign. Thus, the x-components of the centrifugal reactive force acting on each axis would be equal and opposite in direction, and therefore, they would cancel each other. As a result, the substrate having two rotating arms will not impart compressive forces on the corresponding linear track along the x-axis during operation of the system.

[0027] The kinetic energy of the primary transducer can be converted to usable energy twice for every full rotation of the arm(s), i.e. once between the 0° position and the 90° position and once between the 180° and the 270° position. The optimal position of the arm at impact of the substrate with the stationary member can vary but is generally in these ranges. Specifically, as the arm approaches 90° or 270° the gain approaches 0 (see Example, Equation 3). Similarly, the momentum of the substrate at 0° and 180° is also 0 so the gain at those points would also be 0. A suitable secondary transducer can thus be coupled with the primary transducer as a means for converting kinetic and momentum-energy of the substrate and arm into usable energy such as electrical, mechanical, or thermal energy. The secondary transducer can be an electromagnetic induction system, mechanical gear system, heat transfer system, piezoelectric system, or the like. For example, the means for converting the momentum-energy can be an induction coil system, heat dissipater, magnetic brake, friction brake, or linear to rotational motion translator. A heat dissipater can include a substantially inelastic collision between the substrate and a set of bumpers. Heat generated by collision can be converted to energy through heat transfer to produce steam which can be used to drive a turbine, or other similar thermo-electric conversion devices.

[0028] In one specific embodiment of the present invention, the secondary transducer includes at least one induction coil system including a magnet and a complimentary conductive coil. The magnet can be physically coupled to the substrate and oriented to approach the complimentary conductive coil sufficient to induce electrical current therein during movement of the substrate along the oscillatory path. A similar magnet system can be incorporated into the arm as well. Such a secondary transducer can also be utilized as the initiator system by switching the energy source, i.e. from an external battery to energy derived from the zero-point energy field. FIG. **3** illustrates a simplified version of such an electromagnetic-kinetic energy conversion system for the secondary transducer. In particular, a permanent magnet **30** can be coupled to each collision end of the substrate **33** having the arm **32** rotatably coupled thereto. An external induction coil **34** can be oriented at a position (or positions) to allow the kinetic energy of the substrate to be progressively converted to electrical energy at each approach of the substrate to the stationary members **36**. In another embodiment, a piezoelectric material such as a crystal or ceramic can be coupled to the stationary member. The force applied by the substrate to the piezoelectric material can generate an electric potential in response to the applied mechanical stress. Alternatively, the secondary transducer can include a mechanical coupling between the substrate and an energy translator. The energy translator can be a linear-to-rotational motion drive, heat surfacing, or rack and pinion, although other mechanisms may also be suitable.

[0029] After the substrate collides with either of the stationary members, the arm's rotational speed can be replenished by a suitable arm accelerator. For example, an electro-magnet system can be oriented with a permanent magnet **38** at the free end of the arm with a corresponding external induction coil **40**. In this case, the arm can have a t-shape to allow the permanent magnet to be oriented substantially in-line with the magnetic field produced by the external electro-magnet (although opposite signs). This allows for a maximum transfer of kinetic energy to the arm from the electro-magnet acceleration system. Alternatively, the permanent magnet and induction coil can be swapped. Typically, the t-portion **42** can have substantially equal mass on either end such that the center of mass lies along the arm axis. This electro-magnet can impart an impulsive torque to the arm in either the second or fourth quadrant (or at any point right after the collision of the substrate with a stationary member) as the permanent magnet attached to the arm passes closely to the electro-magnet. The advantage of this approach is that the arm's rotation will be maintained substantially by electro-magnetism without additional gears or mechanical losses due to the friction of such gears. This replenishment of the rotational speed of the arm can optionally be achieved by a motor in the second and fourth quadrant (or at any point right after the collision of the substrate with a stationary member) by using pulsed technology, wherein the power to the motor is only turned on in the second or fourth quadrant.

[0030] In operation, the movement of the substrate can follow a linear oscillatory path having two endpoints while the arm(s) follows a cyclic path such that translational motion of the substrate in a y-direction along the oscillatory path substantially coincides with translational motion of the arm in the y-direction. Furthermore, the arm has two theoretical maximum energy transfer positions, the positions occurring twice for every cycle of rotation of the arm. Actual maximum energy transfer positions can be empirically determined and a collision swing angle adjusted to obtain a substantially maximum in the usable energy, depending on the specific design, i.e. relative masses, arm length, rotational velocity, etc.

[0031] There are at least two factors that impact the overall maximum energy gain of the system. For example, the substrate's final kinetic energy before collision with a stationary member partly determines the maximum energy gain of the system. Maximum energy gain is also determined by the angular displacement of the arm at the time of the collision, the angular velocity of the arm, the linear velocity of the substrate prior to collision and the relative masses of the arm and substrate.

[0032] During operation of the system, a full cycle of rotation of the rotator can be divided into the four conventional quadrants counter-clockwise. Upon start-up, the arm is initiated with a battery driven motor (or equivalent, such as an electro-magnet system) to reach a terminal velocity while holding the slider substrate stationary. The terminal velocity is determined by the friction in the system and the power transfer capabilities of the device that delivers power to the rotator to keep it rotating. After the rotator has reached this constant velocity, integrated sensors in the system release the slider just prior to the rotator arriving at its 0 degree position. The slider will begin to accelerate when the y-component of the centrifugal reactive force acting on the physical vertical axis attached to the slider is greater than any static friction force between the slider and its linear track. The angle of the rotator with respect to the x-axis at which angle the slider begins to accelerate is denoted as phi. During this first quadrant rotation of the rotator, the power to the motor can be optionally turned off so that the rotator continues to rotate on its own rotational inertia.

[0033] The distance between the front and back secondary transducers or stationary members can be adjusted such that the slider "collides" with this secondary front transducer when the rotator has rotated an angle less than 90 degrees (e.g. 15° to 75° although other ranges may be useful such as about)45° with respect to the x-axis which gives a maximum transfer of energy.

[0034] In one embodiment, the secondary transducer can comprise a linear generator. The linear generator can include a coil or set of coils receiving the magnets attached to the slider, and all of the electronic and electrical circuitry associated with the linear generator must be able to handle a brief impulse of power if the slider is to come to a near stop quickly. The linear generator can be designed of sufficiently robust materials and capacity to handle this power surge. Alternatively, the secondary transducer can include a thermal conversion system or a piezoelectric device, as previously discussed. More particularly, the stationary members and substrate can be designed to provide a substantially inelastic collision such that much of the kinetic energy of the substrate is converted to heat or electricity. In a thermal conversion process, the substrate and stationary member can accordingly be thermally linked to a water reservoir such that water is heated to steam, which drives an electrical generator.

[0035] A thermal conversion process may be more effective for a large scale energy conversion system. A piezoelectric conversion process may be more useful for a small scale energy conversion system, such as an energy conversion system used in a micro-machine or other type of micro-electro-mechanical system (MEMS).

[0036] After the slider comes to a complete stop after the collision of the slider with a stationary member a pulsed power source can be used to replenish the speed of the rotator back to its initial speed. There will typically be a loss in speed of the rotator due to friction and a replenishment of the speed of the rotator must happen twice every cycle after every collision of the slider with a stationary member.

[0037] Based on the guidance provided herein, a speed of the rotational motion, relative masses of the arm and the substrate, geometry of the arm, and the geometry of the substrate can all be designed such that zero-point energy is utilized to maintain the movement of the substrate. Non-limiting examples of specific variables which can be adjusted include aerodynamic shape of the arm and substrate, length of the arm, materials of construction, density of substrate and arm, and the like.

[0038] Theoretical Background

[0039] Without being bound to any particular theory, it is thought that the principles of operation of the present invention are governed by a theoretical backdrop described in more detail below. In summary, this theoretical backdrop indicates that the momentum influx to the primary transducer is a result of radiation pressure due to scattering in part of the electromagnetic momentum-energy contained within the zero-point field of space opposite to the centripetal acceleration of the arm. The systems of the present invention can be sized and incorporated into a wide variety of applications which are currently occupied by conventional energy sources, e.g. batteries, power generators, fuel cells, and so forth. A more in depth description of one theory follows; however, it is understood that the following description is not exclusive, exhaustive or definitive of the underlying inventive concept.

[0040] We begin a discussion with a rotating point particle with a mass of m_1, and denote it as the rotator. One end of the rotator is attached to a vertical axis by a mass-less wire of length r, so that the rotator rotates freely counter-clockwise around this axis with two degrees of freedom in a plane parallel to the earth. The vertical axis is rigidly attached to a second object denoted as the slider with mass m_2. The slider is constrained to move along a linear track with one degree of freedom, coincident to the y-axis of an x-y Cartesian coordinate system. Initially, the axis of rotation is set at the origin of the coordinate system.

[0041] The rotator is aligned coincident with the x-axis of the x-y coordinate system, such that the rotator is located at 180 degrees with respect to the x-axis. The slider presses against a back bumper so that the slider cannot move in the negative y-direction. An impulse is applied on the rotator in the negative y-direction, causing the rotator to rotate counterclockwise. The rotator rotates until it passes the 0 degrees point, and the slider moves in the positive y-direction at some angle after this 0 degrees point. Immediately prior to the movement of the slider, the initial tangential velocity of the rotator is denoted as v_i. A short time interval later as the slider moves in the positive y-direction, the slider is allowed to make an inelastic collision with a front bumper at some angle θ of the rotator with respect to the x-axis. The tangential velocity of the rotator prior to the collision of the slider is denoted as v_α. The post-collision tangential velocity of the rotator is denoted as v_f. The linear velocity of the slider prior to the collision of the slider is denoted as v_s.

[0042] The initial tangential kinetic energy of the rotator is:

$$KE_{rotator\ initial}\frac{1}{2}m_1v_i^2 \quad (1).$$

[0043] With respect to the laboratory frame this represents the initial energy of the rotator-slider system. As the slider accelerates forward in the positive y-direction under the action of the y-component of the centrifugal reactive force on the axis, both the slider and the rotator acquire an equal instantaneous linear velocity in the positive y-direction, and therefore, a linear kinetic energy with respect to the laboratory frame. By the conservation of energy, the tangential kinetic energy of the rotator must decrease, such that:

$$\Delta KE_{rotator}=KE_{linear\ slider}+KE_{linear\ rotator} \quad (2).$$

Or:

$$\frac{1}{2}m_1v_i^2-\frac{1}{2}m_1v_\alpha^2=\frac{1}{2}m_2v_s^2+\frac{1}{2}m_1v_s^2 \quad (2a).$$

[0044] Rearranging, we have:

$$\frac{1}{2}m_1v_i^2-\frac{1}{2}m_1v_\alpha^2=\frac{1}{2}m_2v_s^2+\frac{1}{2}m_1v_s^2 \quad (3).$$

[0045] That is, by the conservation of energy the pre-collision total kinetic energy observed in the system must equal the initial kinetic energy of the rotator.

[0046] Upon collision of the slider with the front bumper, the kinetic energy of the slider equal to $\frac{1}{2} m_2 v_s^2$ is essentially converted to thermal energy. The linear kinetic energy of the rotator is accounted for as follows.

[0047] Taking θ as the angle of the rotator at the time of collision, and by application of the Pythagorean Theorem, we have:

$$\frac{1}{2}m_1v_s^2=\frac{1}{2}m_1\sin^2\theta v_s^2+\frac{1}{2}m_1\cos^2\theta v_s^2 \quad (4).$$

[0048] The first term on the right side of the above equation represents the kinetic energy of the slider transformed to thermal energy upon collision of the slider. It is reasonable to assume that the energy described by the second term transfers and adds to the tangential kinetic energy of the rotator.

[0049] The tangential kinetic energy of the rotator just prior to the collision is:

$$KE_{rotator\ \alpha}=\frac{1}{2}m_1v_\alpha^2 \quad (5).$$

[0050] Adding the second term on the right of equation 4 to equation 5 to obtain the final post-collision tangential kinetic energy of the rotator, the answer would be:

$$KE_{rotator\ post\ collision}=\frac{1}{2}m_1v_\alpha^2+\frac{1}{2}m_1\cos^2\theta v_s^2 \quad (6).$$

[0051] However, the above equation is incorrect because it was assumed the second term could be used in equation 4 to obtain the final result. This equation, derived from the Pythagorean Theorem, is correct from a conservation of energy perspective, but it cannot be used for post-collision analysis. The post-collision tangential kinetic energy of the rotator must first be obtained by vector addition of vector entities.

[0052] The correct procedure is as follows. Just prior to the collision of the slider, the rotator has a linear velocity in the positive y-direction equal to the linear velocity of the slider. Thus, the rotator has a linear momentum in the positive y-direction equal to:

$$p_{rotator}=m_1v_s \quad (7).$$

[0053] At collision, a part of this momentum is transferred to the front bumper or the earth, and the amount of momentum transferred is equal to:

$$p_{bumper}=\sin\theta m_1v_s \quad (8).$$

[0054] By the conservation of angular momentum the remaining momentum is transferred to the rotator, such that there is an increase in the post-collision angular momentum of the rotator, equal to:

$$m_1v_fr=m_1v_\alpha r+m_1\cos\theta v_sr \quad (9).$$

[0055] Dividing both sides of the above equation by m_1 and r, we obtain:

$$v_f=v_\alpha+\cos\theta v_s \quad (10).$$

[0056] Using the above, the correct expression for the final post-collision tangential kinetic energy of the rotator is derived, equal to:

$$KE_{rotator\ pst\ collision}=\frac{1}{2}m_1v_\alpha^2+m_1v_\alpha\cos\theta v_s+\frac{1}{2}m_1\cos^2\theta v_s^2 \quad (11).$$

[0057] Now, recalling equation 6, we have:

$$KE_{rotator\ post\ collision}=\frac{1}{2}m_1v_\alpha^2+\frac{1}{2}m_1\cos^2\theta v_s^2$$

[0058] Subtracting the above two equations, the difference is obtained as:

$$m_1v_\alpha\cos\theta v_s$$

[0059] Recalling equation 3:

$$\frac{1}{2}m_1v_i^2=\frac{1}{2}m_1v_\alpha^2+\frac{1}{2}m_2v_s^2+\frac{1}{2}m_1v_s^2$$

[0060] Substitute equation 4 into the last term of the above, giving:

$$\frac{1}{2}m_1v_i^2=\frac{1}{2}m_1v_\alpha^2+\frac{1}{2}m_2v_s^2+\frac{1}{2}m_1\sin^2\theta v_s^2+\frac{1}{2}m_1\cos^2\theta v_s^2$$

[0061] Regroup the above as follows:

$$\frac{1}{2}m_1v_i^2=\left(\frac{1}{2}m_2v_s^2+\frac{1}{2}m_1\sin^2\theta v_s^2\right)+\left(\frac{1}{2}m_1v_\alpha^2+\frac{1}{2}m_1\cos^2\theta v_s^2\right) \quad (12).$$

[0062] This is the correct equation for the total energy of the system prior to the collision of the slider. Now take equation 12 and substitute equation 11 for the last two terms in the last parentheses, giving the total energy of the system after the collision of the slider:

$$KE_{system\ final}=\left(\frac{1}{2}m_2v_s{}^2{}_{te}+\frac{1}{2}m_1\sin^2\theta v_s{}^2{}_{te}\right)+\left(\frac{1}{2}m_1v_\alpha^2+m_1v_\alpha\cos\theta v_s+\frac{1}{2}m_1\cos^2\theta v_s^2\right) \quad (13).$$

[0063] Where, the subscript represents the thermal energy transformed from kinetic energy after the collision of the slider.

[0064] The left side of equation 12 represents the initial tangential kinetic energy of the rotator or the initial total energy of the system prior to collision. Equation 13 represents the total energy of the system after the collision. Clearly, there has been a gain in the total energy of the system by the amount of:

$$\Delta E = m_1 v_\alpha \cos\theta v_s$$

[0065] Substituting v_β for $\cos\theta v_s$, the above can be expressed as:

$$\Delta E = m_1 v_\alpha v_\beta$$

[0066] By the first law of thermodynamics there must be an influx of energy-momentum to the system to account for this gain in energy. One possible explanation for the influx may be found in a paper that postulates inertia is due to a time rate change of incoming momentum flux to an accelerating object from the vacuum energy-momentum of space (A. Rueda & B. Haisch, *Contribution to inertial mass by reaction of the vacuum to accelerated motion*, Foundations of Physics, Vol. 28, No. 7, pp. 1057-1108 (1998) which is incorporated herein by reference). The paper states:

[0067] We demonstrate that from the point of view of a nearby inertial observer there exists a net energy and momentum flux (Poynting vector) of ZPF radiation transiting the accelerating object in a direction necessarily opposite to the acceleration vector. The scattering opacity of the object to the transiting flux creates the back-reaction force customarily called the inertial reaction.

[0068] If the above is true, then at the time of the collision of the slider an influx of momentum from the vacuum transits the rotator in the positive y-direction, opposite to the instantaneous linear de-acceleration of the rotator and slider in the negative y-direction. A portion of this momentum, equal to $m_1 \cos\theta v_s r$, transfers to the rotator and increases its angular momentum by an amount found in equation 9, which was derived as a consequence of the conservation of angular momentum.

[0069] It has been known since the last century that energy has inertia implied by Einstein's equation $E=m_0c^2$. Rearranging the equation, we see the mass equivalent of energy expressed as $E/c^2=m_0$. That is, energy in the form of radiation can interact with physical objects as if the energy had the properties of material objects—momentum, etc. Hence, if we assume space is filled with an irrepressible average minimum vacuum energy as predicted by the Heisenberg uncertainty principle in part composed of electro-magnetic radiation, the interaction of accelerating objects with the photons comprising this radiation could indeed create a reaction force. For example, a photon contains momentum equal to:

$$p = hv/c$$

[0070] It is conceivable that photons "colliding" with the rotator opposite to the instantaneous linear de-acceleration of the rotator could transfer part of their momentum to the rotator. And if this were true, along with a transfer of momentum, energy would necessarily transfer also. For example, in the relativistic expression relating the relationship between kinetic energy and momentum we have:

$$(K+m_0c^2)^2 = (pc)^2 + (m_0c^2)^2$$

[0071] Reduced to the Newtonian limit, the above can be expressed as:

$$K = (p)^2/(2m_0)$$

[0072] Hence, any increase in the angular momentum of the rotator due to this transfer of momentum from the vacuum must be accompanied by an increase in kinetic energy with respect to a laboratory frame.

[0073] The above explanation is more plausible than any Machian explanation. One may incorrectly argue that the increase in energy is due to linear frame-dragging, the so-called Lens-Thirring effect, predicted by the general theory of relativity. To date, the Gravity Probe B experiment has not conclusively proven this effect, but even if it did, it would not have any bearing on this discussion. The frame-dragging effect is only observed in the de-accelerating frames of the rotator and the slider as the slider collides with the front bumper. It is not observed in the frame of the laboratory because the mass of the universe is obviously not accelerating with respect to this frame. To insist this effect must apply to the laboratory frame would violate the principle of relativity by implying the de-accelerating frames of the rotator and slider are preferred frames and the effects observed in these frames must be imposed in the frame of the laboratory. An explanation that only applies to the laboratory frame is demonstrated below.

Example

[0074] An experiment was performed to test if energy gain occurred in a rotator-slider system. The experiment tested two hypotheses. The momentum influx hypothesis (MIH) asserted there would be a gain in the post-collision rotational energy of the rotator, and therefore, a gain in the energy of the system as a whole by the action of an influx of energy-momentum to the system via inertia. The null hypothesis or classical hypothesis (CH) asserted there would be no gain in energy of the post-collision rotational energy of the rotator, and therefore, there would be no gain in the system as a whole. The null hypothesis was designated as the classical hypothesis because it takes the classical Newtonian assumption that inertia is an intrinsic property of matter, and therefore, could never affect a gain in energy of any system. The momentum influx hypothesis takes the position that inertia is an extrinsic property of matter a link to the vacuum energy of space under the right conditions. In the experiment the rotator is a physical object. The equations derived in this paper were derived for a point particle. Thus, we must modify the equations previously demonstrated by including the moment of inertia of the rotator.

[0075] Expressed mathematically, the CH maintains the following:

$$\tfrac{1}{2}I\omega_i^2 = \tfrac{1}{2}m_2v_s^2 + \tfrac{1}{2}m_1\sin^2\theta v_s^2 + \left(\tfrac{1}{2}I\omega_\alpha^2 + \tfrac{1}{2}m_1\cos^2\theta v_s^2\right) \quad (1).$$

[0076] The above essentially states that the post-collision energy of the rotator, the terms in parentheses, when added to the other terms, equals the initial rotational kinetic energy of the system. Thus, the energy of the system is conserved.

[0077] The MIH is expressed mathematically as:

$$E_{final} = \frac{1}{2}m_2v_s + \frac{1}{2}m_1\sin^2\theta v_s^2 + \left(\frac{1}{2}I\omega_\alpha^2 + \frac{I\omega_\alpha\cos 0\theta v_s}{r} + \frac{I\cos^2\theta v_s^2}{2r^2}\right). \quad (2)$$

[0078] The terms in parentheses above represent the post-collision energy of the rotator derived from the conservation of angular momentum. When added to the remaining terms, the above is greater than equation 1 by the following, which expresses the gain in energy of the system:

$$\Delta E = \frac{I\omega_\alpha \cos\theta v_s}{r} + \frac{I\cos^2\theta v_s^2}{2r^2} - \frac{m_1\cos^2\theta v_s^2}{2}. \tag{3}$$

[0079] Where:

[0080] I=the moment of inertia of the rotator

[0081] ω_α=the angular velocity of the rotator prior to collision

[0082] θ=the angle of the rotator at the time of collision

[0083] v_s=the linear velocity of the slider prior to collision

[0084] r=the distance from the axis to the center of mass of the rotator

[0085] In the experiment the post-collision energy of the rotator was measured and compared to the MIH and CH prediction. The collected data is in Table 1 while the results are presented in Table 2.

[0086] In Table 1 and Table 2 the following terms are defined:

[0087] ω_α=the measured angular velocity of the rotator prior to collision

[0088] θ=the measured angle of the rotator at the time of collision

[0089] v_s=the measured linear velocity of the slider prior to collision

[0090] ω_i=the measured initial angular velocity of the rotator

[0091] ω_f=the measured final post-collision angular velocity of the rotator

[0092] ke_i=the measured initial kinetic energy of the rotator

[0093] ke_α=the measured kinetic energy of the rotator prior to collision

[0094] ke_f=the measured final kinetic energy of the rotator after collision

[0095] m_1=the mass of the rotator

[0096] m_2=the mass of the slider

[0097] I=the moment of inertia of the rotator

[0098] r=the radial distance from the axis to the center of mass of the rotator

[0099] m_1 was 3.89 kg, m_2 was 1.97 kg, l was 0.403 kg m^2, and r was 0.314 m.

TABLE 1

ω_α	θ	v_s	ω_i	ω_f	ke_i	ke_α
8.80	32.0	0.294	9.81	9.72	19.4	15.6

7.33	45.0	0.622	9.62	9.17	18.6	10.8

TABLE 2

ke_f(J)	MIH Prediction (J)	CH Prediction (J)	Net over CH (J)
19.0	20.2	15.73	3.3
18.0	21.5	15.87	2.1
15.3	16.2	11.08	4.2
16.9	16.3	11.20	5.7

[0100] As can be seen, the net gain over CH predicted values was from about 13% to about 50%.

[0101] The foregoing detailed description describes the invention with reference to specific exemplary embodiments. However, it will be appreciated that various modifications and changes can be made without departing from the scope of the present invention as set forth in the appended claims. The detailed description and accompanying drawings are to be regarded as merely illustrative, rather than as restrictive, and all such modifications or changes, if any, are intended to fall within the scope of the present invention as described and set forth herein.

What is claimed is:

1. An energy conversion system for extracting energy from the zero-point field of space, comprising:

a) a primary transducer including a substrate having an arm rotatably coupled to the substrate, said substrate being confined to move along an oscillatory path; and

b) a secondary transducer operatively associated with the primary transducer, the secondary transducer converting kinetic energy of the substrate and arm to usable energy.

2. The system of claim **1**, wherein the oscillatory path is a linear track defined by a pair of resilient stationary members oriented on both ends of the linear track.

3. The system of claim **1**, further including a drive motor operatively associated with the arm and configured to initiate rotational motion of the arm and sustain the rotational motion at a critical angular velocity.

4. The system of claim **2**, wherein the substrate has a substrate mass (m_2) and the arm has an arm mass (m_1) such that a ratio of m_2 to m_1 is chosen to maximize a gain in kinetic energy (ΔKE) of the substrate and the arm.

5. The system of claim **1**, further comprising a secondary arm rotatably coupled to the substrate and having a secondary axis of rotation spaced apart from an axis of rotation of the arm, said secondary arm being coupled to the arm such that both the arm and the secondary arm rotate at a common angular velocity and opposite rotational directions, and wherein the secondary arm has a substantially identical mass and dimensions to that of the arm.

6. The system of claim **5**, wherein the secondary arm rotates about a common axis of rotation with the arm.

7. The system of claim **1**, wherein the secondary transducer includes at least one induction coil system including a magnet and a complimentary conductive coil, such that the magnet is physically coupled to the substrate and oriented to approach the complimentary conductive coil sufficient to induce electrical current therein during movement of the substrate along the oscillatory path.

8. The system of claim **1**, wherein the secondary transducer includes piezoelectric material operable to convert a force applied by the substrate to the secondary transducer to an electric potential in response to applied mechanical stress.

9. The system of claim **1**, wherein the secondary transducer includes a mechanical coupling between the substrate and an energy translator.

10. The system of claim **9**, wherein the energy translator is a linear to rotational motion drive, heat surfacing, or rack and pinion.

11. The system of claim **1**, wherein the usable energy is mechanical, thermal and/or electrical energy.

12. An energy conversion system for extracting energy from the zero-point field of space, comprising a means for extracting momentum-energy from vacuum by the action of inertia and a means for converting the momentum-energy to usable energy operatively associated with the means for extracting momentum-energy.

13. The system of claim **12**, wherein the means for extracting momentum-energy is a substrate having an arm rotatably coupled to the substrate which substrate is confined to move along an oscillatory path.

14. The system of claim **12**, wherein the means for converting the momentum-energy is an induction coil system, heat dissipater, magnetic brake, friction brake, or linear to rotational motion translator.

15. A method of extracting energy from the zero-point field of space, comprising:

a) inducing rotational motion of an arm rotatably mounted to a substrate which is confined to move along an oscillatory path and wherein the rotational motion is sufficient to impart movement of the substrate along the oscillatory path; and

b) converting momentum-energy of the substrate to usable energy.

16. The method of claim **15**, wherein a speed of the rotational motion, relative masses of the arm and the substrate, geometry of the arm, and the geometry of the substrate are designed such that zero-point energy is utilized to maintain the movement of the substrate.

17. The method of claim **15**, wherein the inducing is accomplished by a drive motor.

18. The method of claim **15**, wherein the movement of the substrate follows a linear oscillatory path having two endpoints and the arm follows a cyclic path such that translational motion of the substrate in a y-direction along the oscillatory path substantially coincides with translational motion of the arm in the y-direction.

19. The method of claim **18**, wherein the arm has two theoretical maximum energy transfer positions that occur twice each full cycle of the arm, corresponding to two angles of the arm with respect to an x-axis, which angles occur simultaneously at the time of collision of the substrate with a stationary member.

20. The method of claim **15**, wherein the step of converting is accomplished by inductive coupling of conductive wire and at least one magnet.

21. The method of claim **15**, wherein the usable energy is mechanical, thermal and/or electrical energy.

22. The method of claim **15**, further comprising inducing rotational motion in a secondary arm in an opposite direction to that of the arm such that motion along the oscillatory path of each of the arm and the secondary arm substantially coincide with each other.

23. A method of extracting energy from the zero-point field of space, comprising:

a) inducing multi-mode motion in a primary transducer along an oscillatory path, wherein the multi-mode motion includes a primary translational motion and a secondary motion such that abrupt changes in the primary translational motion are sufficient to impart a momentum influx to the secondary motion; and

b) converting the momentum influx to usable energy.

24. The method of claim **23**, wherein the momentum influx is a result of radiation pressure due to scattering in part of the electro-magnetic momentum-energy contained within the zero-point field of space opposite to centripetal acceleration of the arm.

(57) **ABSTRACT**

Existing spacecraft accelerate by ejecting propellant, and VTOL craft hover by creating violent downdrafts of air. We describe a propellantless propulsion system that can achieve practical spaceflight and hovering flight by exchanging momentum with normally unobservable quantum particles that pervade all of space.

High-polarizability nanoparticles with electromagnetic resonances in the petahertz range are formed into nanoantennas, and exposed to high fields in the terahertz range. The fields increase the density of naturally occurring vacuum fluctuation (VF) petahertz oscillations in the nanoantennas. The nanoantennas are assembled into arrays, such that their naturally occurring zero-point oscillations are amplified by the terahertz fields, producing enhanced oscillations in VF densities during each petahertz oscillation period that interfere constructively in the intended direction of emission. This causes the VF oscillations to partially convert to travelling waves that emit from the system, creating an imbalance in VF pressure and urging the device to move in the direction of least pressure.

BACKGROUND OF THE INVENTION

[0004] Apparatus is described for achieving propellantless propulsion of space and air vehicles, by causing the naturally occurring radiation pressure (RP) of virtual quantum particles to become greater on one side of the claimed device than the opposite side, thus causing movement in the direction of least pressure. The apparatus may also provide hovering flight of airborne vehicles without requiring violent downdrafts of air, or exert force on various objects as may be useful for industrial processes or meet other needs.

BRIEF SUMMARY OF THE INVENTION

[0005] Hitherto, space vehicles have been propelled by the ejection of propellant; and aircraft, by thrusting against air. The application presents viable alternatives whereby such vehicles may achieve motion by absorbing from free space, amplifying, and re-emitting unidirectionally, the virtual radiation of so-called virtual particles such as vacuum fluctuations (VFs). The claimed means of doing so are as follows:

1. Electromagnetic oscillators generate above zero-point VF densities in high-polarizability nanoparticles such as buckyballs or other fullerenes. The nanoparticles being formed into nanoantennas, either singly, or in combination, by, for example, joining about twelve C3840 buckyballs to form full-wave linear petahertz nanoantennas.
2. A numerically large number of such nanoantennas are formed into 2D arrays, which are then stacked to form 3D arrays.
3. The nanoantennas are so spaced apart as to oscillate in a phase relationship such that they interfere constructively in a given direction here termed the forward direction, and destructively to the rear and sides.
4. This transforms the forward-directed VF oscillations from standing waves to travelling waves, which then move or shunt along the nanoantennas, combining their amplitudes as they do so, until they emit from the final tier of nanoantennas.
5. The VF flow creates a below zero-point VF pressure in the rearward nanoantennas, causing a replenishing flow of VF waves to be drawn into the device from the rearward free space surroundings, thus allowing the forward flow of VFs through the device to continue for as long as the device is appropriately energized.
6. The device thus produces thrust via the generation of radiation pressure somewhat analogously to a photon rocket. However, photons require hv joules to create them, but only supply hv/c newtons of radiation pressure, where h is Planck's constant, v the photon frequency, and c the speed of light in free space. This means that the thrust to power ratio is an abysmal 1/c newtons per joule at best. It is hard to imagine anything less efficient, for even moving a single skateboard would require the entire output of numerous power stations to be converted into photons! By contrast, VFs are freely provided by nature, and, in principle, require no unrecoverable energy to create them except in so far as their creation generates pressure. It follows that the propulsive efficiency of a VF radiating device can, in principle, approach a limit of one newton of thrust per joule.

[0006] We wish to point out that while we have described VFs as travelling through space much as do photons, we consider this to be only a mental image, since the behavior of VFs in free space is an unobservable; it being only their interactions with matter that are capable of direct detection and measurement.

[0007] What is known, and what is claimed here as an operating principle of the invention, is that VFs possess a momentum of ½hv/c, and their unidirectional emission from the forward antennas in the claimed device must create a reactive force acting on the device, urging it rearward.

[0008] It will be shown that the claimed device permits electrical equipment oscillating in, for example, the terahertz frequency range, to generate VF emissions in the petahertz range.

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] FIG. **1**A shows twelve high-polarizability buckyballs combined to form a nanoantenna.

[0010] FIG. **1**B shows in side view, sixty-four FIG. **1**A nanoantennas formed into a 3D array or stack, comprising eight vertical columns, each with eight horizontal tiers.

[0011] FIG. **1**C shows the stack of FIG. **1**B in front view.

[0012] FIG. **1**D shows a stack in side-view, in which the nanoantennas are randomly spaced.

[0013] FIG. **1**E shows antennas formed from buckyballs in two 8×8 tiers.

[0014] FIG. **1**F shows an 8×8 matrix of nanoantennas constructed from buckyballs, mounted on a substrate to form long-wire antennas.

[0015] FIG. **2** shows eight stacks as FIGS. **1**B & **1**C combined together to form a "thrust generator," by which is meant an assemblage of stacks so assembled, constructed, and energized by electromagnetic devices, as to emit VF radiation unidirectionally.

[0016] FIG. **3** shows schematically how a motor may be constructed by mounting suitably modified FIG. **2** thrust generators around a rotatable shaft, such that their radiative outputs are directed tangentially to the shaft.

[0017] FIG. **4** Shows FIG. **2** thrust generators powered by an electromagnetic terahertz frequency generator.

[0018] FIG. **5** shows an electromagnetic generator output waveform, and the waveforms it generates in two nanoantennas that are oscillating in a particular phase relationship with each other.

[0019] FIG. **6** shows typical polar field diagrams for two antennas separated by a given number of wavelengths. The larger diagram sums their combined output.

Special Terms Used

[0060] Tier: A 2D nanoantenna array.

Stack: A 3D nanoantenna array.

Thrust generator or TG: A device in which a number of stacks are assembled such that they combine their radiative outputs.

VFs: Vacuum fluctuations.

Forward direction: The direction in which the radiative output of the stacks combines constructively. Opposite: Rearward direction, associated with destructive interference, or redirection of output.

DETAILED DESCRIPTION OF THE INVENTION

Introduction

[0061] It is well established that quantum entities known as vacuum fluctuations (VFs), pervade all of free space at a mean energy density known as the zero-point. The VFs are, in fact, virtual photons, the word virtual denoting that their transitions do not conserve energy, and thus render their energy inaccessible [1]. This assumption of inaccessibility is being challenged by some ingenious proposals, however, what concerns us here is the known fact that VFs possess momentum which is constantly traded back-and-forth with real-world particles [1, 2, 5, 8-10, 12, 26]. This indicates that one-waying VFs in guiding structures may produce unidirectional propulsive effects.

[0062] It may seem unphysical to suggest that VF momentum can be accessible while VF energy is not. However, while the energy is held to be inaccessible because the vacuum has no lower state the VFs can fall into (i.e, there can be no change of state), linear momentum is equivalent to a harmonic oscillation of zero hertz and is not comparably restricted.

[0063] One might also note that the term virtual does not mean unreal! In fact, so-called virtual transitions have very real effects. To name but one example, the Van der Waals attractions between molecules—the very glue that holds our entire world together—arises from virtual transitions [3].

[0064] We require no weird physics to explain the operating principles of the claimed devices. We first consider the known fact that the relationship for the interaction of an induced dipole with an electric field is provided by $E_\alpha=(-\frac{1}{2}\alpha E^2)$, where

E_α is the potential energy in joules, E is the electrical field strength in volts per meter, and α the electrical polarizability of the dipole in Cm^2/V [1, 4, 5, 9-11]. The units are SI, and may be applicable to both to static and dynamic polarizabilities [5]. The minus sign (discarded from here on), indicates the resulting force is attractive.

[0065] What is particularly relevant for our purposes is that this term provides the potential energy that appears between a polarizable particle and a conductive wall due to the action of VFs alone [1, 7-11]. It can also produce the force between two polarizable particles that is likewise due to VFs, as will be developed below.

[0066] These matters suggested to the applicant that if giant-polarizability nanoparticles were formed into 3D nanoantenna arrays, and their E_α energy components cycled up and down by externally applied fields, this might produce rapid oscillations of their associated VF field densities, causing the nanoantennas to emit VFs unidirectionally, in rather the same way that conventional antenna arrays [20] emit radar and signal-carrying beams when driven in phase-quadrature.

[0067] Before proceeding with practical details, we address the following theoretical concerns.

The Reality of Vacuum Fluctuation Pressure and Momentum Exchange.

[0068] It is a known fact that VFs possess a momentum of ½hv/c newton per fluctuation that can exert pressure on real-world particles [1, 2, 10, 14, 15, 25, 26]. Further, VFs are widely believed to exist independently of matter [1, 2, 9, 11, 12, 26], and thus exert a pressure on any object reflecting a VF field. This pressure equals 2u for incident radiation reflected from a plane surface on one side, where u is the free-space or zero-point energy density. The pressure reduces to u if the radiation is evenly divided between both sides of the reflector, and equals u/3 for an isotropic distribution, in which case both sides are referred to by definition [2, 12, 14].

[0069] It follows that if any means is found to create a greater VF pressure one side of an object than the other, the object will be urged to move in the direction of least pressure. This is the simple principle underlying the proposed propulsive apparatus.

[0070] Some analysts have a reluctance to accept—despite the overwhelming number of papers that now routinely define vacuum quantum electrodynamics in terms of vacuum fluctuation theory—that fluctuating vacuum fields exist in the absence of physical sources. However, Peter Milonni, while discussing laser linewidths in his definitive book *The Quantum Vacuum [*1], refers to "the external vacuum field" transmitting through a laser mirror, undergoing amplification as it propagates to the second mirror, and then being reflected (p194). He then writes:

> **[0071]** "It is worth noting again that our calculation of the Schawlow-Townes linewidth assumes that the vacuum field is transmitted, reflected, and amplified in the same way as fields of "real" photons, i.e., fields defined in terms of excited states of the field. The transmission and reflection properties of the vacuum field are consistent with the fact (see {P.M's} Sections 2.4 and 6.2) that the spatial variations of the quantized field are the same as those of the classical field subject to the same boundary conditions. The fact that the vacuum field may be amplified follows from the fact that its contribution to the laser linewidth is more or less interchangeable with the contribution from spontaneous emission: If spontaneously emitted radiation inside the cavity is amplified by the gain medium, then so too must the vacuum field entering the cavity." (p197-198.)

[0072] It may be particularly noted, that Milonni describes the VFs as being amplified, reflected, and transmitted without undergoing any conversion into real photons. This directly contravenes the expectations of some pundits that VFs transmitting from such apparatus would so convert into photons.

[0073] Another commonly raised objection to the idea that VFs possess radiation pressure independently of matter, is that the Casimir effect can be negative.

[0074] For those unfamiliar with the subject matter, we explain that the Casimir effect or force is most typically demonstrated when two metal plates are separated from each other by a submicron distance. When this is done, a small attractive force is observed, the reason being, generally speaking, is that there are less VF modes between the plates urging them apart, than there are VF modes outside the plates urging them together. Thus the latter VF modes produce the greater radiation pressure, resulting in a net inward force.

[0075] However, there are a number of geometries and configurations in which the pressure in small gaps exceeds the external pressure. This has led to the dubious argument that the pressure is a special case of the van der Waals molecular forces. But lately Hushwater [27], has demonstrated that, in such cases, the negative pressure is due to there being a greater number of VF modes within the gap than without.

[0076] Lifshitz has also shown, in a seminal paper, that intermolecular forces may cease to be additive when the dielectric constants are high [35].

[0077] We therefore claim the VFs will exert pressure on the claimed devices. By way of example, we look ahead to the device shown in FIG. **2**. It is not necessary to understand how it works at this time, but merely accept that the arrows show the flow of VFs through the apparatus; and that the apparatus will amplify or pressurize the VFs when appropriately energized. We assume isotropic VF distributions, and consider only horizontal pressures since all others will balance out. We determine the forces acting on the device as follows:

[0078] (1). If VFs enter the device from the left as shown, pass through the stacks as **10**, and exit back to the left without amplification or loss, they will produce a pressure of u/3 newton per square meter urging the device to the right. This pressure will, of course, equal the zero-point pressure of free space.

[0079] (2). Some VFs that would otherwise enter the device are scattered back by the left-facing edges of cover plates **42** & **38**, the four leftmost stacks as **10**, and the stub-like leftmost vertical sections of the three leftmost partitions as **30**. These scatterings will exert an ambient pressure of u/3 N/m^2 urging the device to the right.

[0080] (3). VFs approaching from the right, and encountering the right-hand cover plate **40** will exert the same pressure of u/3 urging the device to the left.

[0081] (4). The above pressures clearly sum to zero because the left-hand and right-hand areas are identical. Thus, the net pressure=(1)+(2)−(3)=0.

[0082] (5). However, if the VFs entering the device as (1) are amplified by their passage through the stacks as **10**, their pressure will clearly rise above ambient or zero-point levels. For example, if pressure (1) is doubled by amplification, the resultant net pressure will be approximately 2×(1)+(2)−(3)=(1)≅u/3 N/m^2, urging the device to the right. The "nearly equals" is inserted because the emitted distribution will no longer be isotropic.

A Small Sample of Relevant Patents Issued by the US Patent Office

[0083] The US Patent Office has granted a number of patents to inventors attempting to harness VFs or zero-point energy to create new energy sources and the like. The applicant does not consider any to anticipate his own claims, but offers the following as a small sample.

1. In 1996 Dr. Frank Meade was granted U.S. Pat. No. 5,590,031 which claimed two spherical antennas resonating passively at different frequencies, that gathered VF radiation from free space, thereby generating a VF radiation beat-frequency to be supplied to electrical devices and perform work. Thus the USPO recognized the possibility that VF radiation exists freely in space and that it may be harnessed for useful purposes, even if there is an appearance of building a "free energy" device. A matter that does not concern us in the present application.

2. In 1987 Federico Capasso was granted U.S. Pat. No. 4,704,622 which claimed devices that could harness VFs to enhance the tunneling abilities of electrons in solid-state devices utilizing quantum wells. Although the present application makes no claims involving VFs in such electronic devices, which operate by electron-hole formations, such a VF aid to tunneling is similar in principle to the present inventor's claim that VFs can shift progressively along chained nanoantennas, especially those that lie within each others near-fields.

3. In 1977 Grigg was granted U.S. Pat. No. 4,004,210 for devices that utilized zpe pressure to drive fluctuations through electronic devices in a cold to hot direction. He insisted for many years that such a thing need not violate the second law, and he may have gained some support, since a multi-national company is reported to have a "nanorectifier" program which at least sniffs at such feasibilities. Again, the US Patent Office has recognized the possibility that VF radiation pressure may perform work, and we note that accepting that VF pressure may drive energy from cold to hot is a far greater leap than to accept that appropriate devices can simply transform VF oscillations from standing waves to travelling waves and emit from the claimed apparatus. However, it is to be understood that the present inventor makes no claim for any device that violates physical law.

4. In 2002 F. Pinto was granted U.S. Pat. No. 6,477,028 which claimed apparatus for storing "Casimir force energy" (i.e, VF radiation) by, in one case, linking two "Casimir force generating boundaries" while varying the physical parameter of the environment separating them. This is another example of the US Patent Office accepting the possibility that VF radiation can be treated as a working medium for producing useful effects.

Giant Polarizability

[0084] Returning to the earlier discussion regarding the construction of nanoantennas using materials possessing large electrical polarizabilities, we find that carbon fullerenes such as buckyballs [6], and materials such as $Na_{14}F_{13}$ possess so-called giant polarizabilities that can be some three orders of magnitude greater than the run of the mill values customarily found in handbooks [13]. We note particularly that Gueorguiev et al [6], have calculated that a 3840-atom buckyball has what they term an α_{LCAO} figure (based on calculations involving linear combinations of atomic orbitals), of 33,731 $Å^3$, or 3.75×10^{-36} Cm^2/V in the SI system. Therefore, by way of example, we consider the use of these buckyballs to construct the nanoantennas.

The Antenna Stacks and their Construction

[0085] FIG. **1**A shows twelve buckyballs as **1** mounted together to construct a linear nanoantenna **2**. FIG. **1**B shows, in front view, sixty-four such nanoantennas as **2** formed into eight columns as **4**, each with eight horizontal (2D) tiers as **5**, to create a 3D nanoantenna array or stack **6**. The antennas are embedded in a dielectric or aerogel substance **8**.

[0086] FIG. **1**C shows stack **6** in side view, revealing forty of the previous eight-tier columns as **4**. It is envisaged that such stacks might consist of about 26 tiers as **5** each consisting of ~10^{16} antennas per square meter, all emitting broadside in the preferred case (i.e, vertically in FIGS. **1**B & **1**C), and embedded in a dielectric or aerogel substance **8**.

[0087] FIG. **1**D shows a stack **9** in which can be seen about sixty spherical nanoantennas as **10** spaced randomly, and embedded in a dielectric or aerogel substance **8**. It will be described later.

[0088] FIG. **1**E shows 128 antennas as **2*a*** formed from buckyballs as **1**, in two 8×8 tiers which may be stacked—as many as required—between substrates as **100**, two of which are shown. An advantage of such an assembly is that there is no requirement to embed the antennas in a dielectric. Such nano-structures can be caused to self-assemble, as is explained below.

[0089] FIG. **1**F shows an 8×8 matrix of nanoantennas as **2***b*, formed from buckyballs as **1**, mounted on substrate **100**, in extended lengths that may act operatively as what are known to those versed in the arts, as long-wire antennas. Thinner versions of substrate **100** may be used to brace longer antennas at regular intervals.

[0090] Buckyballs may be readily formed into a well-ordered 2D array by attaching them to a nanomesh. One such suitable nanomesh consists of a single layer of boron nitride, another is graphene. A boron nitride mesh can be formed by self-assembly if an operator exposes a rhodium or ruthenium surface to borazene at high temperatures in an ultra-high vacuum [21]. Such nanomeshes have a remarkable ability to trap fullerenes, and also other particles such as molecules, nanoparticles, and metallic clusters, in their pore matrix, such that each pore seats one buckyball.

[0091] A nanomesh described in the above reference had a periodicity of 3 nanometers, and a 2 nanometer hole diameter. However, similar nanomeshes can now be tailored to meet a wide range of geometric, and also electrical specifications, such as whether conductive or insulating parameters are required.

[0092] A second method by which an operator may build a 2D buckyball array on a nanomesh is by spraying [23]. For example, purified arc buckyballs such as may be purchased from Carbon Solutions, California, USA, can be added to an aqueous solution of 1% sodium dodecyl sulfate (SDS), at a concentration of 0.02 to 0.05 mg buckyballs per ml of solution. The resulting suspension is mixed by sonication for one hour, and then sprayed onto the nanomesh in a fine mist by means of a Paasche airbrush. It is necessary to heat the nanomesh to 100 degrees centigrade to prevent the formation of large droplets. It is then soaked in water to remove residual SDS.

[0093] An operator may also produce 2D buckyball arrays by dissolving the buckyballs in benzene, and depositing them on the surface of doubly-distilled water [22]. The solvent is allowed to evaporate, leaving behind a self-assembled film of buckyballs. The film is then compressed by a barrier that is moved at microscopic speed, applying a pressure of about 0.02 N/m to the film as it does so. The film can then be transferred to a substrate using the Schaefer method, in which the film is moved horizontally by contact with a hydrophobic plate.

[0094] It will be apparent that such 2D buckyball arrays may be readily mounted one above another to form the stacks required for the present application. This requires that the spacing between each 2D array be such as may best develop the electrical phase relationships to be described later. This may be accomplished by using much the same airbrush spraying technique as revealed above to coat the buckyball arrays with a dilute solution cadmium telluride, using such amount as will produce a dielectric film of the desired thickness once the solvent has evaporated. A second 2D buckyball array may then be placed on the film, and the above operations repeated until the desired number of tiers has been formed.

[0095] Although FIG. **1**A shows the use of only a single column of buckyballs to construct an antenna, it will be understood that multiple parallel columns may be used to provide a thicker antenna, thereby, for example, increasing the bandwidth. Alternately, multiple buckyballs or other fullerenes might be used singly, or clustered to form spherical antennas. Thereby, for example, abolishing any need for the axial alignment that non-spherical antennas may require. Such particles may also operate as point-source antennas.

[0096] Buckyballs link together naturally to form chains as FIG. **1**A when formed into a suspension in suitable solvents. Droplets of such a suspension may then be formed onto a substrate, subjected to DNA hybridization, and finally immobilized with random orientations either on or between Au electrodes. The nano-chains may then be straightened naturally by the shear-forces generated by an evaporating droplet [32].

[0097] Alternately, the substrate may be etched with linear cavities of suitable length and width to trap buckyballs and form them into antennas as FIG. **1**A. The cavities being spaced apart lengthwise and sidewise as necessary to form tiers as **5** FIG. **1**B & **1**C. The substrate may then be rinsed clean of all other fullerene material. At which time a similar substrate may be mounted atop it, and such stacking of substrates continued until a 3D stack of suitable tier count has been assembled, as described above.

The Thrust Generator

[0098] FIG. **2** shows in schematic, seriously not to scale side-view, the mid-cross-section of a device we term a thrust generator (TG). The figure shows eight stacks as **11**. The arrows show paths taken by the VFs as they flow through the TG. It can be seen that they appear from the left, and flow into the stacks either through three input channels as **12** or lower channel **14**, vertical channel **16**, and three input channels as **18**.

[0099] After passing through the stacks and becoming pressurized (powering the device is described in the next section), the VFs enter horizontal channel **20** at the top of the figure, either directly, or via the three horizontal output channels as **22**, and the vertical channel **24**, or alternately via three output channels as **26**, and vertical channel **28**. They then exit the device to the left.

[0100] Six slanted partitions as **30**, slanted vertical partition **32**, and vertical partition **34** prevent the VF pressure from back-flowing to the input regions after emerging from the stacks. (Note that the stacks are one-way devices, and cannot themselves backflow).

[0101] The partitions also prevent the VFs emerging from a lower stack from passing into the one above—a matter that would reduce thrust generation efficiency, as is explained later.

[0102] The top, bottom, and rear covers **36**, **38**, & **40** further prevent VFs from leaking in or out of the system. It will be understood that there are also two side covers preventing any sideways leakage, both covers being in sealing contact with the full length of covers **36**, **38**, & **40**. One cover faces the viewer, but cannot be shown since the view is cross-sectional, the other is at the rear of the drawing, but is omitted for clarity.

[0103] The various partitions and cover plates comprise jointly the first and second radiation guiding structures mentioned in the Claims.

[0104] The TG can also generate thrust if the VFs passing through the stacks flow straight through the device from left to right instead of entering from the left and reversing back upon themselves as shown. This can be arranged by removing right-hand cover-plate **40**, and placing a partition similar to partition **34** at the left opening of topmost channel **20** to seal it off.

[0105] It will be apparent that the permanent direction of thrust can be reversed simply by rotating the device horizontally until the emission is to the right instead of to the left as shown in the drawing. To ensure balanced thrust during the transition, the thrust might be generated by an even number of identical TGs, half of which rotate clockwise, and the other half, anti-clockwise.

The Terahertz Generator

[0106] For the purposes of example and calculation, the TGs are here described as being powered by rapid oscillation of external fields in the form of THz radiation. Lower frequencies will not be efficient, and higher infrared frequencies may produce heating problems. However, the generation of THz radiation is a comparatively new field, and although there are a number of somewhat standardized systems to choose from that have undergone significant development, non of them seem very satisfactory. These systems include gyrotrons; backward wave oscillators; far-infrared, quantum, and free-electron lasers; and synchrotrons [28].

[0107] Unfortunately, those that can develop significant power, such as gyrotrons, are inefficient and bulky, while others are currently limited to milliwatt outputs, and/or can only operate at 50K or worse. All emit only narrow beams.

[0108] Fortunately, two new choices have now been demonstrated. Both involve the development of nano-emitters formed into 2D matrices with huge packing densities, in rather similar fashion to the nanoantenna tiers **5** of FIGS. **1**B & **1**C, and can potentially produce square-meter beams from flat, pancake-like substrates, if required. The first uses superconducting Josephson junctions, and is able to generate THz radiation [29]. However, the temperature is limited to 50K, and despite the high packing densities, the output power density still appears to be low.

[0109] The second choice, developed at UCSD, involves micromachining nano-vacuum cold triodes and similarly forming high packing-density matrices. Emission power densities exceeding 100 W/cm^2 may be possible at room temperature. The frequency was limited to 10 Ghz in 2002[30]. However, a later paper [31] indicates that frequencies of 10 THz should be possible. We therefore select the UCSD system as our currently preferred THz emitter with which to power the TGs.

Generating Rotary Motion

[0110] It will be apparent that if TGs are mounted on a rotatable shaft they will capable of generating rotary motion around the shaft. FIG. **3** shows a device configured for this purpose: The drawing shows TG assemblies **50** & **52**, each of which contains two pairs of TGs separated by a central partition as **90**. The TGs are geometrically tweaked but conceptually identical versions of that shown in FIG. **2**. They can be seen more clearly in FIG. **4** which is described below. They are butt-joined to the end-faces of rod **54** via flanges as **56**. Rod **54** is centrally secured to rotatable shaft **58**, which is mounted on support arms **60** and **62**, which are attached to base **64**.

[0111] The two slip-rings **66** and **68** deliver electrical energy from a conventional power supply to a THz generator **70** similar to the UCSD device, via conventional brushes and supply-wiring that is not shown. The generator emits THz radiation directly into the TGs, causing them to amplify and unidirectionally emit VF radiation as previously described. The radiation is emitted tangentially to shaft **58**, and thus urges the rotatably mounted TG assemblies **50** & **52** to rotate clockwise (top TG moving away from viewer) in the drawing.

[0112] The residual THz power that exits the TGs to the right in the drawing, passes into structure **72** which is so contrived as to either absorb the radiation and dissipate it as heat, or convert it back to electrical energy and return it to THz generator **70**.

[0113] The VFs enter the TGs from free space through the exposed leftmost face of TG **50** in the drawing, and thus also through the unseen exposed rightmost face of TG **52**. These faces are covered by mesh filters consisting of partially shown frames as **76** and wires as **78** which prevent the escape of THz radiation but freely transmits PHz radiation; it being the case that the mesh filters, in combination with partitions **80** (bottommost for TG assembly **50**), partitions **82** (rearmost for TG assembly **50**), and partitions **84** (topmost for TG assembly **50**), function as a THz waveguide. From which it follows that the filters are so contrived as to present essentially the same reflective characteristics to the THz emissions as do the three partitions.

[0114] Suitable mesh filters can be supplied by Microtech Instruments located in Oregon, USA. If the output of THz generator **70** is polarized either S-wise or L-wise, it can be blocked by evenly spaced microwires with a diameter to spacing ratio of about three or four, having appropriate axial alignment to the THz beam. An unpolarized beam will require a mesh.

[0115] FIG. **4** shows the FIG. **3** TGs in top schematic view. Central partition **90** separates two identical TGs **92** & **94**. The end cross-sections of mesh wires as **78** can be seen, as can the side sections of mesh frame **76**. Two sockets **98** & **100** supply the generator with electrical energy from a conventional power supply, as indicated by the two arrows.

[0116] As stated, the TGs are conceptually identical to that shown in FIG. **2** with minor changes in dimensions. etc. Thus, numbering as in FIG. **2**, there are 32 stacks as **11***a*, with diagonal partitions as **30***a*, and **32***a*, and partitions as **34***a*; the same arrangement of main channels as **14***a*, **16***a*, **20***a*, **24***a*, and **28***a*; and smaller channels as **12***a* and **22***a*.

Buckyball Resonance

[0117] The nanoantennas described earlier may be tuned to have a natural resonance at a frequency of about 2 PHz (10^{15} Hz). This should be perfectly feasible since, for example, C60 buckyballs are known to have a giant resonance (with a surprisingly large bandwidth) at about 2 Phz [15]. Bertsch et al also predict "a giant collective resonance at an unusually high energy of ~20 eV" (about 5 PHz), for C60 buckyball clusters [27]. It is also well known that fullerene resonances can be readily enhanced, or tweaked this way or that, by the insertion of additional elements in the form of one or two atoms [4, 24]. The very intense fields created by the THz generator can amplify these PHz oscillations in accordance with the $\frac{1}{2}\alpha E^2$ relationship described earlier, and thus increase the density of the VF PHz fields associated with the buckyballs, in sync with the field oscillations.

[0118] We assign the generator field intensity E_{gen} a peak value of 3E+5 V/m, this being the most likely level at which polarization saturation will occur in the nanoantennas, i.e, the point at which polarizability ceases to increase very much with increasing field strength. It might be thought that fields this high will cause electrical breakdown in the airgaps in the TGs. However, it has been found that micro and nano airgaps have a very high resistance to breakdown, this being because their short path lengths prevent ion-cascading. Also discharges are limited by work-function type effects [16, 17].

Obtaining Constructive Interference

[0119] Antenna arrays emit unidirectionally because they are (typically) spaced a quarter-wavelength apart along their emission axes (the exact distance is usually tweaked for best results), and so driven that there is a time-lag of 90° between each successive antenna in that direction (i.e, they are driven in phase-quadrature), causing the antenna emissions to interfere constructively, and thus combine in the forward direction or direction of declining phase angle; while interfering destructively in the reverse direction, and very largely so to the sides.

[0120] This can best be seen in FIG. **5** in which E_{int}, denoted by the thin solid line, is that part of the generator voltage E_{gen} which appears directly across the buckyballs which form the nanoantennas. Its amplitude is given by

$$E_{int} := \left(\frac{3\cdot\varepsilon_s}{2\cdot\varepsilon_{bb}+\varepsilon_s}\right)\cdot E_{gen},$$

where $\in_{bb}=4$ is the dielectric constant of the buckyballs, and $\in_S=4$ is that of the stacks, for both the generator input frequency and the full VF bandwidth. It follows that

$$\left(\frac{3\cdot\varepsilon_s}{2\cdot\varepsilon_{bb}+\varepsilon_s}\right) = 1,$$

in which case $E_{int}=E_{gen}=3E+5$ V/m.

[0121] Also in FIG. **5**, waveforms E_0 and E_{90} show the nominal enhancement above zero-point level of the petahertz-frequency voltages induced in the nanoantennas by E_{int}. E_0 is a waveform that is initially in phase with E_{int} and is denoted by the thick solid line, where $E_0=\cos(\theta)\cos(\theta\cdot r)$, and r is the ratio of the generator stack VF wavelength $\lambda_{ip.s}$ to the average VF stack wavelength $\lambda_{av.s}$, where $\lambda_{ip.s}/\lambda_{av.s}=30$.

[0122] E_{90}, denoted by the broken line, is a waveform that leads E_0 by 90 degrees due to the phase-quad spacing of the nanoantennas, and is thus given by $E_{90}=\cos(\theta)\cos(\theta\cdot r+\pi/4)$.

[0123] In accordance with the principle of pattern multiplication, E_0 and E_{90} flow through any given stack in the form of travelling waves. They combine their amplitudes, the phase difference between them disappearing in the forward direction of flow. It can thus be seen that the stacks behave somewhat as do amplitude modulators, with E_{int} simulating a carrier wave, while the induced VF waves behave analogously to signal waves.

[0124] For the purpose of example we set the tier-to-tier spacing between the antennas (center-to-center) at $0.8\lambda_{av.s}$. This rather large spacing is necessitated by the fact that the center-to-center distance between two C3840 buckyballs placed in contact is about $0.65\lambda_{av.s}$

[0125] When antennas are stacked this close together relative to their diameter, those skilled in the arts usually determine the exact distance of separation required to produce constructive interference in the forward direction by simple experimentation. It is likely that the best experimentally determined figure will not differ significantly from that assumed above [36].

[0126] Short gap lengths have the advantage that all antenna-antenna transitions take place within the reactive near-field distance in which—by definition—the transitioning particles remain in the virtual state [18, 19, 34]. The nominal reactive near-field distance of full-wave antennas is $\lambda/2\pi$, so the combined overlap distance of two such antennas$=\lambda/\pi=0.318\lambda$. We note that this is about twice the edge-to-edge gap length between the antennas, as developed above.

Calculations

[0127] We set the maximum VF frequency v2 that we propose to transmit unidirectionally through the stacks at 10 PHz. This lies slightly above the ultraviolet transmission fade of lithium fluoride, which we consider to be a suitable dielectric for the stacks; but since the thickness of the stacks is only about 170 nm, the fade should not be a problem.

[0128] We assume a modest VF bandwidth=(v2−v1)/½(v2+v1)=0.2, where v1 is the minimum frequency and so equals 8.2 PHz. The average frequency v_{av} thus equals 9.1 PHz, corresponding to a free-space wavelength $\lambda_{av.o}=33$ nm. We have assumed that the permittivity of the stacks $\in_S=4$, we further assume it is lossless, in which case the v_{av} wavelength in the stacks$=\lambda_{av.s}=(\lambda_{av.o}/\sqrt{\in_s})=16.5$ nm. This figure provides the principle measuring stick for the stacks. We now set the generator frequency v_g at 3 THz, which therefore has a stack wavelength$=\lambda_{ip.s}=(c/v_g\sqrt{\in_S})=500$ nm.

[0129] Recalling that, as mentioned above, the average THz to PHz wavelength ratio=30, it is apparent that the phase difference between any two neighboring nanoantennas should best be considered only an average figure, and that a certain variance in individual phase measurements is to be expected for any given antenna pair.

[0130] However, this is not a serious matter: FIG. **6** shows that unidirectional beam-forming of antenna pairs need not depend critically on the antenna phasing having any particular precise value. Here polar graphs labeled ¼, ½, ¾, & 1 show field amplitudes of two half-wave antennas separated by the same numbers of wavelengths, and driven respectively with phase difference of 90, 180, 270, and 360 degrees. These fields are combined additively in larger graph Σ, which shows the combined fields to be stronger to the left of the diagram than the right by a factor of about 2:1. It follows that reasonable variances in antenna phasing will not seriously affect the beaming efficiency of the TGs. Note that when large numbers of antennas are stacked together, as in the TGs, the rightward and side emissions shown in the above diagrams will be almost zero, since the diagrams are correct for only two antennas.

[0131] It should be particularly noted that the graphs—particularly graph Σ—indicate that if antennas are randomly spaced in a stack as FIG. **1**D, they will still generate significant unidirectional emissions, as long as their maximum spacing is limited to about one wavelength.

[0132] This indicates that stacks suitable for use in TGs might be formed, by, for example, mixing buckyballs into a solvent into which a dielectric has been dissolved, and spraying the solution onto a substrate with an airbrush as described earlier, but this time using a buckyball concentration sufficient to produce an average spacing within the sprayed dielectric of about a half wavelength, once the solvent has evaporated. The amount of spray used should be sufficient to build a stack of whatever final thickness is desired, since it will not be formed by layering as before. The FIG. **1**D stack, formed in this way, should emit radiation rather as shown in the FIG. **6** Σ combined-fields figure, excepting that, as stated, there will be no emission in the rearward direction, and very little to the sides.

[0133] We can now calculate the PHz emission rates: We have mentioned that when E_0 and E_{90} flow through a stack in the form of travelling waves, they combine their amplitudes. It follows that since there are 26 nanoantennas in each stack, the nominal total forward flow=26 E_0 (or for that matter, =26 E_{90}). which, in either case, equals the peak value of E_{int}.

[0134] We therefore define the average nominal energy flow along any single column of antennas in any given stack as

$$\varepsilon_{an.av} = \frac{1}{2}\alpha_{C3840} \cdot 26 \cdot \left(\frac{E_{int.pk}}{\sqrt{2}}\right)_{17}^{216} = 2.2E\text{-}24 \text{ J},$$

where $E_{int.pk}$ is, of course, the peak value of E_{int}. Losses will be dealt with later.

[0135] We assume that this virtual energy is emitted in the form of VFs. Therefore, to obtain the total nominal virtual energy output E_{st} per second of a one-square meter stack, and thus the total power of the emitted VFs, we multiply $\in_{an.av}$ by the number of antennas per tier=$n_{a.tr}$=1.47E+16, and the generator frequency $v._{av}$. Thus:

$E_{st}=\in_{an.t}\times n_{a.tr}\times v_{av}=2.9E+8$ Watt per stack per square meter.

[0136] This energy is virtual, and, of course, has no particular observable effects in and of itself. However, since it is the energy of the emitted VFs (½hv per fluctuation), we have only to divide by c to obtain the radiation pressure (hv/2c per fluctuation), which will have real effects as explained earlier. Thus:

[0137] $p_{rp}=E_{st}/c=0.98$ newton per square-meter stack. We now divide by the constant of gravitation to get kilograms:

[0138] $p_{rp}/g=0.1$ kg per square-meter stack, disregarding losses, which will be discussed in the next section.

[0139] If this figure seems high, we should bear in mind that it is produced by ~$\mathbf{10}^{17}$ nanoantennas possessing giant polarizabilities, driven at near breakdown-limited field strengths, and operating at unprecedented THz frequencies.

[0140] Finally, we estimate the thrust output for a really large TG: And since, as already stated, the thickness of a 26 tier stack is only about 170 nm, we can readily pack about 10^6 square-meter stacks one above another, to form a one-cubic meter TG. The thrust output of such a structure=p_{m3}=0.1×10^6=10^5 kg.

[0141] It is instructive to compare p_{kg} to the pressure p_{freeS} produced by free space VF densities acting on one side of a one square-meter mirror. It is determined by first calculating the energy density of free space E_{freeS} [22]:

$$E_{FreeS} = \left[\frac{h'}{8 \cdot \pi^2 \cdot c^3} \cdot (\omega_2^4 - \omega_1^4)\right] = 4.26E + 5 \text{ J/m}^3,$$

from which the pressure, as described earlier:

$$F_{FreeS} = \left(\frac{1}{3} \cdot \frac{E_{FreeS}}{g_m}\right) = 14490 \text{ kg/m}^2,$$

[0142] where ω2 & ω1 are v2 and v1 expressed in radians, h'=h/2π is the gravitational constant, and the 1/3 is an adjustment for isotropic distribution. This frequency range lies beyond the opacity region of many materials, but is, of course, fully balanced by the internal structural strengths of materials with higher frequency absorptions—the structural strengths being themselves due to internal VFs and other virtual photons.

[0143] We might note that the ratio of stack radiation pressure p_{ip} to p_{freeS} is only about (7×10^{-6}):**1**. This means that the stacks shown in FIGS. **2**, **3**, & **4** will need only proportionately narrow channels (as **12**, **22**, & **14**, **20**, **28**, **24**, **16**; FIG. **2** and their FIG. **4** counterparts), set between them to provide for VF flow.

Losses

[0144] We identify the principle losses and their associated decimal multiplier as follows:

1. Imperfect transparency of the dielectric in the stacks: ≅×0.75.
2. Unwanted VF scattering in the stacks and losses due to imperfect antenna positioning: ≅×(1/3).
3. Reduction in effective radiation pressure due to beam spread to either side of normal: ≅[1−cos(30)]=×0.846.
4. Lack of proportionality between increase of nanoantenna VF potential energy with $E._{int}^2$ due to polarization saturation: ≅×(2/3).
5. Finally we estimate inefficiencies in the transmission of VFs from antenna to antenna in the tiers, by making a reasonable assumption that the antennas transmit their outputs one to another in the forward direction with a decimal efficiency η=0.95. The output of the first antenna will then=η^1=0.95, the combined output of the first and second will=($\eta^1+\eta^2$)=1.853, and so on. This can be solved for any number of tiers by the summand below, which shows the gain g_n for any number of tiers n_{ts} per stack. An assumption that n_{ts}=26 looks good, in which case:

$$g_n = \left[\sum_{n_{t.s}=(n_{t.s})}^{0} \eta^{n_{t.s}}\right]_{=14}.$$

[0145] We therefore add a loss factor ≅×(14/26).

6. Finally we add ×0.7 for miscellaneous losses.

[0146] The summed losses therefore

[0147] ≅(0.75×(1/3)×0.846×(2/3)×(14/26)×0.7)=0.053.

[0148] Adjusting by this factor, we find that the net pressure per stack

[0149] =$p_{rp.net}$=0.1×0.053=0.0053 kg/m^2,

and similarly, the net pressure developed by a cubic meter TG=5300 kg.

Closing Remarks

[0150] It is to be understood that the calculations presented here are only intended as a rough guide to the performance of the apparatus. And further, that even though numerous characteristics and advantages of the present invention have been set forth in the above description, together with details of the structure and function of the invention, the disclosure is illustrative only, and changes may be made in detail, especially in matters of shape, size and arrangement of parts within the principles of the invention, to the full extent indicated by the broad general meaning of the terms in which the appended claims are expressed.

[0151] Further, the theories given above as to why VFs may usefully exchange momentum with propulsive devices, are provided in the spirit of presenting information as best the inventor is able, but it should be understood that the operation of the devices described here do not necessarily depend on the theories being correct as stated.

What is claimed is:

1. A method for producing thrust in a mass without ejection of tangible propellant, said method comprising the following steps;

- a) absorbing from free space the virtual radiation of so-called virtual particles such as vacuum fluctuations by means of antenna-like structures;
- b) causing said virtual radiation to flow along a plurality of said antenna-like structures whilst its field intensities are caused to be amplified;
- c) causing said virtual radiation with said amplified field intensities to be returned to free-space or emitted by said antenna-like structures;
- d) said emitting of said virtual radiation being further caused to occur in an essentially unidirectional or beam-like pattern;
- e) it being well known to those versed in the arts that said virtual radiation generates real radiation pressure, it is thus the case that said unidirectional emission of said virtual radiation causes said radiation pressure to urge said mass to move in accordance with Newton's third law, whereby the force exerted on said mass by said radiation pressure, and the reverse, are simultaneous; equal in magnitude; opposite in direction; and in the same line;
- f) steps (a) through (d) are accomplished by causing said antenna-like structures to be:
  - (1) appropriately structured such that they are tuned and suitably resonant in the targeted frequency range of said virtual radiation;
  - (2) appropriately spaced apart or contiguous, such that they are suitably linked one to another with regard to efficiency of radiative transfer, and so as to cause such particular electromagnetic phase differences between neighboring said antenna-like structures as may be required;
  - (3) appropriately energized by rapidly oscillating externally generated electromagnetic fields, such that said rapid oscillations of external fields cause said field intensities of said virtual radiation to vary cyclically.

2. The method recited in claim **1** wherein the following means are provided;

- a) first means for converting to travelling waves, the standing waves, otherwise known as oscillations, of said virtual particles, that are known to exist resonantly in numerous forms of matter;
- b) second means to provide that said numerous forms of matter take the form of nanoparticles, examples of which are fullerenes, nanotubes, spherical nano-clusters, and the like; along which said travelling waves may flow, growing in strength due to said amplification of field intensities as they do so, in approximate proportion to the number of said nanoparticles;
- c) third means whereby said travelling waves, on reaching an end-point of said nanoparticles, here termed the emitting end, are caused to undergo said emission into free space;
- d) it being the case that said flow of said travelling waves, and their said emission from said emitting end of said nanoparticles, causes said field intensities to become depleted to below zero-point level at or near another end-point, here termed the receiving end, at or near which said flow begins;
- e) it being further the case that said absorbing of said virtual radiation from free space occurs at or near said receiving end, thereby combining with, and contributing additively to, said flow of said travelling waves to said emitting end of said nanoparticles; thus restoring said depletion below zero-point level of said virtual radiation, and increasing it to above zero-point level;
- f) it being understood that while said depletion and said increasing of said virtual radiation is described in cause and effect terms for clarity, they are essentially simultaneous;
- g) it therefore being the case that said absorption; said flow of said travelling waves to said emitting end; and resultant said emission, may continue for as long as suitable apparatus for accomplishing the several means of this claim is appropriately energized.

3. Apparatus for accomplishing the goals of claim **2**, comprising:

- a) said nanoparticles such as may possess large electrical polarizabilities, particularly those formed from one of the general classes of materials possessing so-called giant polarizabilities; two such examples being various fullerenes and $Na_{14}F_{13}$ molecules;
- b) whereby said nanoparticles are so formed and positioned in said apparatus, as to function operatively as nanoantennas, such as may be best suited for said absorbing, said amplifying, and said emission of said virtual radiation;
- c) by said nanoantennas, is meant electromagnetic antennas, of comparable size to the wavelengths of said virtual radiation, said wavelengths being sub-micrometer in length; it being understood that said nanoantennas may also be linked contiguously one to another to form what is known to those versed in the arts as long-wire antennas;
- d) first means of assembling said nanoantennas into 2D arrays, by which is meant a single layer of said nanoantennas, multiple in number, that are formed into rows and columns in a single plane;
- e) second means of assembling said 2D arrays by a stacking process to form 3D arrays; the spacing between said nanoantennas in said 2D and said 3D arrays being such as may best permit said nanoantennas to accomplish said absorption, said amplification, and said unidirectional emission, of said virtual radiation, when energized by said rapid oscillations of external fields;
- f) to better illustrate, we mention that one well known example of said spacing of antennas in beaming arrays is that which permits said antennas to operate in phase-quadrature.

4. means of assembling said 3D arrays of claim **3** in a modified format, said modification being that said nanoantennas placed within it are spaced apart somewhat randomly instead of being arranged in a regular order as disclosed in **3**(*d*) and **3**(*e*); it being the case that the construction of said modified 3D array may thus be simplified;

a) it being further noted that the maximum spacing between said nanoantennas in said modified 3D arrays should be of the order of a wavelength of said virtual radiation.

5. Means whereby said 3D arrays of claims **3** may be placed one above another, or otherwise in close proximity to each other, while being separated by first radiation guiding structures, such that said emissions of one said 3D array is prevented from becoming the input of another; this being undesirable because such series feeding may lower the efficiency of said emission of said virtual radiation.

6. Means whereby said 3D arrays of claims **3** are housed within second radiation guiding structures that may be minor additions to said first radiation guiding structures, and which so direct said virtual radiation entering said first and second guiding structures, that said virtual radiation is emitted in the direction from which it first entered;

a) that is to say, that if, by way of example, said virtual radiation enters said first and said second guiding structures from the left, it also exits to the left, thus being scattered back about 180 degrees; thereby approximately doubling said radiation pressure acting on said first and said second guiding structures;

7. Apparatus for generating said rapid oscillations of external fields of claim **3**, for the purpose of energizing said 2D and said 3D arrays, whereby said rapid oscillations of external fields cause said amplification of said field intensities of said virtual radiation in said nanoantennas;

a) said apparatus for generating said rapid oscillations of external fields consisting of a high-packing density matrix of nano-emitters such as nano-vacuum cold triodes or the like, able to emit beamed electromagnetic radiation at terahertz frequencies or greater; said beams being capable of covering large areas of a square-meter or more when required for such applications as thrusting heavy vehicles;

b) means for developing electrical phase differences in said oscillations of said virtual radiation in said 2D and said 3D arrays, whereby said emissions of neighboring said nanoantennas interfere constructively in a preferred direction, and interfere destructively, or nearly so, in all other directions.

8. Means whereby said apparatus of claim **7** for generating said rapid oscillations of external fields may operate at a frequency lower than the frequency of said oscillations of said nanoantennas, while non-the-less causing said emissions of said nanoantennas at a higher frequency;

a) for example, said apparatus for generating said rapid oscillations of external fields may operate in the terahertz, i.e, 10^{14} hertz frequency range, while causing changes in the amplitude of said oscillations of said virtual radiation of said nanoantennas in the petahertz, i.e, 10^{15} hertz range, thereby producing said emissions at said petahertz range.

9. Means whereby said 3D arrays of claim **3** are rotatably mounted on pivoting means such as a shaft seated on bearings, such that said virtual radiation emitted by said 3D arrays is tangentially directed around said pivoting means, whereby it urges rotation of said 3D arrays around said pivoting means;

a) it being the case that said rotation may convey rotational energy to conventional work-performing devices, by means of gear trains or the like;

b) it being further the case that apparatus for causing said rapid oscillations of external fields may likewise be rotatably mounted on said pivoting means, so as to be in suitable close proximity to said 3D arrays;

c) wherein said apparatus for generating said rapid oscillations of external fields may be energized by conventional power supplies; said power being transmitted by such means as brushes and slip-rings mounted on said pivoting means; inductive transfer of power from a stationary coil to a rotating one mounted on said pivoting means; electrodes immersed in mercury pools, and the like.

(57) **ABSTRACT**

A system is disclosed for converting energy from the electromagnetic quantum vacuum available at any point in the universe to usable energy in the form of heat, electricity, mechanical energy or other forms of power. By suppressing electromagnetic quantum vacuum energy at appropriate frequencies a change may be effected in the electron energy levels which will result in the emission or release of energy. Mode suppression of electromagnetic quantum vacuum radiation is known to take place in Casimir cavities. A Casimir cavity refers to any region in which electromagnetic modes are suppressed or restricted. When atoms enter into suitable micro Casimir cavities a decrease in the orbital energies of electrons in atoms will thus occur. Such energy will be captured in the claimed devices. Upon emergence form such micro Casimir cavities the atoms will be re-energized by the ambient electromagnetic quantum vacuum. In this way energy is extracted locally and replenished globally from and by the electromagnetic quantum vacuum. This process may be repeated an unlimited number of times. This process is also consistent with the conservation of energy in that all usable energy does come at the expense of the energy content of the electromagnetic quantum vacuum. Similar effects may be produced by acting upon molecular bonds. Devices are described in which gas is recycled through a multiplicity of Casimir cavities. The disclosed devices are scalable in size and energy output for applications ranging from replacements for small batteries to power plant sized generators of electricity.

FIG. 8

QUANTUM VACUUM ENERGY EXTRACTION

BACKGROUND OF THE INVENTION

Max Planck proposed the concept of zero-point energy in 1912. The idea was then studied by Albert Einstein and Otto Stern in 1913. In 1916 Walther Nernst proposed that the Universe was filled with zero-point energy. The modern field of stochastic electrodynamics is based upon these ideas.

At that same time the structure and stability of the atom were puzzles. The Rutherford model of the atom was based on analogy to the motions of planets (electrons) around the Sun (the nucleus). However this was not feasible. The orbiting electron(s) would emit Larmor radiation, quickly losing energy and thus spiraling into the nucleus on time scales less than one-trillionth of a second, thereby rendering stable matter impossible. It is now known within the context of stochastic electrodynamics (SED) theory that a possible solution involves the absorption of zero-point energy. It was shown in 1975 by Boyer that the simplest possible atom and atomic state, the hydrogen atom in its ground state, would be in a state of equilibrium between Larmor radiation and absorption of zero-point energy at the correct radius for a classical Rutherford hydrogen atom.

Since this solution was not known in 1913, Niels Bohr followed a different path by simply postulating that only discrete energy levels were available to the electron in an atom. This line of reasoning let to the development of quantum theory in the 1920s. The concept of classical zero-point energy was forgotten for a decade. However the same concept found itself reborn in a quantum context in 1927 with the formulation of the Heisenberg uncertainty principle. According to the principle, the minimum energy of a harmonic oscillator has the value hf/2, where h is Planck's constant and f is the frequency. It is thus impossible to remove this last amount of random energy from an oscillating system.

Since the electromagnetic field also must be quantized in quantum theory, a parallel is drawn between the properties of a quantum oscillator and the waves of the electromagnetic field. It is concluded that the minimum energy of any possible mode of the electromagnetic field, consisting of frequency, propagation direction and polarization state, is hf/2. Multiplying this energy by all possible modes of the field gives rise to the electromagnetic quantum vacuum, which has identical properties—energy density and spectrum—to the classical zero-point energy studied by Planck, Einstein, Stern and Nernst a decade previously.

The line of inquiry involving classical physics plus the addition of a classical zero-point field was reopened in the 1960s by Trevor Marshall and Timothy Boyer and has been named stochastic electrodynamics (SED). SED asks the question: "Which quantum properties, processes or laws can be explained in terms of classical physics with the only addition being a zero-point electromagnetic field." Two of the early successes were a classical derivation of the blackbody spectrum (i.e. one not involving quantum physics) and the discovery that a classically orbiting electron in a hydrogen atom emitting Larmor radiation but absorbing zero-point radiation would have an equilibrium orbit at the classical Bohr radius. An initial approach to this problem by Timothy Boyer (1975) was perfected by H. E. Puthoff (1987). Their analyses treated the orbiting electron as a harmonic oscillator.

This result underwent a major new development with the recent work of Daniel Cole and Y. Zou which simulated the orbit of a classical electron in a true Coulomb field of a hydrogen nucleus and found that such a realistic electron would find itself in a range of distances from the nucleus, in agreement with quantum mechanics, owing to the random nature of the emission and absorption processes. The mean position is at the correct Bohr radius, but the actual distribution of positions very precisely duplicates the electron probability distribution of the corresponding Schrödinger equation in which the electron is regarded as being represented by a wave function. (In the SED representation the electron is "smeared out" not because it is a wave function, but because as a point-like particle it is subject to the continuous perturbations of the electromagnetic quantum vacuum fluctuations.)

A clear consequence of this theory is that a reduction of the electromagnetic quantum vacuum at the frequency corresponding to the orbit of the electron will result in a decay of the orbit since there will thereby be an imbalance in the Larmor radiation vs. absorption.

The electromagnetic quantum vacuum energy spectrum is proportional to the cube of the frequency. If the vacuum energy is suppressed at the frequency of the "normal" orbit of the electron, this will cause the electron to spiral inward to a higher frequency orbit. In this fashion it will then encounter a new equilibrium situation with the electromagnetic quantum vacuum energy spectrum owing to that spectrum's increase with the cube of the frequency.

If the SED interpretation is correct for the hydrogen atom as the analyses of Boyer, Puthoff, Cole and Zou indicate, it must apply as well to all other atoms and their multi-electron configurations. In that case, a transition of an electron from an excited state to a lower energy state involves a rapid decay from one stable orbit to another, not an instantaneous quantum jump. The details of the bases for stability of electron orbits has yet to be determined by SED theory, but the logical extrapolation from the single-electron hydrogen case is clear: electron orbits in all atoms must be determined by an emission vs. absorption balance and thus are subject to modification involving mode suppression of the electromagnetic zero-point field at appropriate frequencies.

It is claimed that modification of electron orbits is in essence the same process as natural transition between energy levels of electrons in atoms and therefore that the energy released in such a process can be captured in the same way as ordinary transition energy.

By moving an atom into and out of a microstructure that suppresses appropriate modes of the electromagnetic quantum vacuum, an extraction of energy from the electromagnetic quantum vacuum may be accomplished. This can be done with micro Casimir cavities.

The electromagnetic quantum vacuum as a real source of energy is indicated by the Lamb shift between s and p levels in hydrogen, van der Waals forces, the Aharanov-Bohm effect, and noise in electronic circuits.

However the most important effect of the electromagnetic quantum vacuum is the existence of the Casimir Force, a force between parallel conducting plates which may be interpreted as a radiation pressure effect of electromagnetic quantum vacuum energy. Electromagnetic waves in a cavity whose walls are conducting are constrained to certain wavelengths for reasons having to do with transverse component boundary conditions on the wall surfaces. As a result, in a Casimir cavity between parallel plates there will be, in effect, an exclusion of radiation modes whose wavelengths are longer than the separation of the plates. An overpressure of electromagnetic quantum vacuum radiation on the outside then pushes the plates together. An extensive literature exists on the Casimir force and the reality of the force has moved from laboratory experimentation to micro-electro-mechanical structures (MEMS) technology both as a problem (so-called "stiction") and as a possible control mechanism.

The exclusion of modes does not begin all at once at the wavelength equivalent to the plate separation, d. Mode suppression will be strongest for wavelengths of d or greater, but will begin to occur as well for wavelengths falling in between the "stairway" d/n, with the effect diminishing as n increases. We propose to use the partial suppression of modes for wavelengths shorter than d occurring in this fashion in order to be able to employ Casimir cavities of the maximum possible physical size.

Researchers have shown that thermodynamic laws are not violated when energy is "extracted" from zero-point energy, as energy is still conserved and the second law is not violated. Cole and Puthoff have carried out and published thermodynamic analyses showing that there is no violation. Indeed, a thought experiment by Forward (1984) showed a simple, but not practical, energy extraction experiment.

In the stochastic electrodynamics (SED) interpretation of the hydrogen atom, the ground state is interpreted as effectively equivalent to a classically orbiting electron whose velocity is c/137. The orbit is stable at the Bohr radius owing to a balance between classical electromagnetic emission and absorption from the electromagnetic zero-point field. This view, first obtained by Boyer (1975) and subsequently refined by Puthoff (1987) has been further strengthened by the detailed simulations of Cole and Zou (2003, 2004) which demonstrate that the stochastic motions of the electron in this interpretation reproduce the probability density distribution of the Schrödinger wave function. Note that one apparent difference between this interpretation and that of quantum mechanics is that in quantum mechanics the 1s state of the electron is regarded as having zero angular momentum, whereas in the SED interpretation the electron has an instantaneous angular momentum of $mcr/137=h/2\pi$. However SED simulations by Nickisch have shown that the time-averaged angular momentum is zero just as in the quantum case owing to the zero-point perturbations on the orbital plane. Thus averaged over enough "orbits" this "classical electron" will fill a spherical symmetric volume around the nucleus having the same radial probability density as the Schrödinger wave function and zero net angular momentum, completely consistent with quantum behavior.

The Bohr radius of the atom in the SED view is 0.529 A (Angstroms). This implies that the wavelength of zero-point radiation responsible for sustaining the orbit is $2*\pi*0.529*137=455$ A (0.0455 microns). It is claimed that suppression of zero-point radiation at this wavelength and shorter in a Casimir cavity will result in the decay of the electron to a lower energy state determined by a new balance between classical emission of an accelerated charge and zero-point radiation at $\lambda<455$ A, where λ depends on the Casimir plate separation, d. Note that the tail end of the quantum probability density of the electron (as well as the SED simulation of Cole and Zou) extends beyond five Bohr radii, so that some change in the energy balance could be accomplished even at considerably longer wavelengths of perhaps 0.1 microns-0.2 microns

Since the frequency of this orbit is 6.6×10^{15} s^{-1}, no matter how quickly the atom is injected into a Casimir cavity the process will be a slow one as experienced by the orbiting electron. We therefore assume that the decay to a new sub-Bohr ground state will involve gradual release of energy in the form of heat, rather than a sudden optical radiation signature.

Since the binding energy of the electron is 13.6 eV, we assume that the amount of energy released in this process would be on the order of 1 to 10 eV for injection of the hydrogen atom into a Casimir cavity of d=250 A or thereabouts (and perhaps even a larger cavity as noted above). Upon exiting the cavity the electron would absorb energy from the zero-point field and be re-excited to its normal state. The energy (heat) extracted in the process comes at the expense of the zero-point field, which in the SED interpretation flows at the speed of light throughout the Universe. We are in effect extracting energy locally and replenishing it globally. Imagine extracting thimbles-full of water from the ocean. Yes, the ocean is being depleted thereby, but no practical consequences ensue.

Since naturally occurring hydrogen at standard temperature and pressure (STP) is a two-atom molecule, a dissociation process would need to precede an injection of hydrogen atoms into a Casimir cavity. We avoid this complication and take advantage of multi-electron modification by working with monatomic (noble) gases which also have the advantage of being safe and inexpensive.

We work with naturally occurring monatomic gases for three reasons:

(1) No dissociation process is required.

(2) Heavier element atoms are approximately two to four times larger than hydrogen and thus can utilize and be affected by a larger Casimir cavity which is easier to fabricate.

(3) Heavier elements have numerous outer shell electrons, several of which may be simultaneously affected by the reduction of zero-point radiation in a Casimir cavity.

The following five noble gases are potentially suitable:
He (Z=2, r=1.2 A)
Ne (Z=10, r=1.3 A),
Ar (Z=18, r=1.6 A)
Kr (Z=36, r=1.8 A)
Xe (Z=54, r=2.05 A).

All of these elements contain ns electrons. He has two 1s electrons. Ne has two each of 1s and 2s electrons. Ar has two each of 1s, 2s, and 3s electrons. Kr has two of each of 1s, 2s, 3s, and 4s electrons. Xe has two of each of 1s, 2s, 3s, 4s and 5s electrons.

Assuming an outermost electron which is completely shielded by the other electrons (a crude assumption), its orbital velocity would scale as $r^{-1/2}$ (the familiar Keplerian period squared proportional to semi-major axis cubed relationship) and thus λ proportional to r/v) will scale as $r^{3/2}$. If that is the case, then the larger radii translate as $r^{3/2}$ into larger Casimir cavities having an effect on the energetics of the outer electron shells. We would therefore expect that a Casimir cavity having d=0.1 microns (or perhaps even as large as one micron would have an effect on reducing the energy levels of the outermost pair of s electrons . . . and possibly also p electrons and intermediate shell s electrons as well.

It is reasonable to expect that a 0.1 microns Casimir cavity would result in a release of 1 to 10 eV for each injection of a He, Ne, Ar, Kr or Xe atom into such a cavity.

According to a Jordan Maclay, who has done theoretical Casimir cavity calculations, a long cylindrical cavity results in an inward force on the cavity. In the "exclusion of modes" interpretation of the Casimir force, this implies that a cylindrical cavity of diameter 0.1 micron would yield the desired decay of outer shell electrons and subsequent release of energy.

It is now recognized that an electromagnetic quantum vacuum field is formally necessary for atomic stability in conventional quantum theory (Milonni 1994). In the field of physics known as stochastic electrodynamics, this concept has been shown by theory and simulations to underlie the ground state of the electron in the hydrogen atom. The classical Bohr orbit is determined by a balance of Larmor emission and absorption of energy from the zero-point fluctuations of the electromagnetic quantum vacuum in SED theory. It follows that upon suppression of appropriate zero-point fluctuations the balance will be upset causing the electron to decay to a lower energy level not ordinarily found in nature with a release of energy during this transition. A Casimir cavity of the proper dimensions can accomplish this suppression of zero-point fluctuations. A Casimir cavity refers to any region in which electromagnetic modes are suppressed or restricted. Upon entering such a properly designed Casimir cavity the electron energy level will shift and energy will be released. Upon exiting the Casimir cavity the electron will return to its customary state by absorbing energy from the ambient zero-point fluctuations. This permits an energy extraction cycle to be achieved at the expense of the zero-point fluctuations. Although it has not yet been proven theoretically, a similar balance of Larmor emission and absorption of energy from the zero-point fluctuations must underlie the electron states of all atoms, not just hydrogen, permitting any atom to be used as a catalyst for extraction of zero-point energy (the energy associated with the zero-point fluctuations). An analogous process is also believed to underlie molecular bonds, yielding a similar energy extraction cycle.

The following is a list of patents that deal with related phenomena:

U.S. Pat. No. 5,018,180, Energy conversion using high charge density, Kenneth R. Shoulders. This concerns the production of charge clusters in spark discharges. It is conjectured that the electrostatic repulsion of charges is overcome in charge clusters by a Casimir-like force. This invention does not deal with energy release from atoms in Casimir cavities and is therefore not relevant to the present invention.

U.S. Pat. No. 5,590,031, System for converting electromagnetic radiation energy to electrical energy, Franklin B. Mead and Jack Nachamkin. This invention does not deal with energy release from atoms in Casimir cavities and is therefore not relevant to the present invention.

U.S. Pat. No. 6,477,028, Method and apparatus for energy extraction, Fabrizio Pinto. Proposes to vary one or more of a variety of physical factors that affect the Casimir force, or by altering any of a variety of environmental factors that affect such physical factors and thereby render a Casimir force system as non-conservative. This invention does not deal with energy release from atoms in Casimir cavities and is therefore not relevant to the present invention.

U.S. Pat. No. 6,593,566, Method and apparatus for energy extraction, Fabrizio Pinto. A method and apparatus for accelerating and a decelerating particles based on particle surface interactions. This invention does not deal with energy release from atoms in Casimir cavities and is therefore not relevant to the present invention.

U.S. Pat. No. 6,665,167, Method for energy extraction-I, Fabrizio Pinto. Similar to U.S. Pat. No. 6,477,028. This invention does not deal with energy release from atoms in Casimir cavities and is therefore not relevant to the present invention.

SUMMARY OF THE INVENTION

A system is disclosed for converting part of the energy of the electromagnetic quantum vacuum available at any point in the universe to usable energy in the form of heat, electricity, mechanical energy or other forms of power. This is accomplished using an effect on the electron configurations of atoms predicted by the theory of stochastic electrodynamics (SED). Within the context of SED theory it is predicted that the electron energy levels in atoms are determined by a balance of Larmor radiation vs. absorption of radiative energy from the electromagnetic quantum vacuum. By suppressing electromagnetic quantum vacuum energy at appropriate frequencies a change may be effected in the electron energy levels which will result in the emission or release of energy. This change in energies is analogous to a standard emission of a photon as an electron makes a transition from an excited to a lower energy state, but on a longer time scale and with the change being a continuous one rather than a “jump” from one energy level to another. Mode suppression of electromagnetic quantum vacuum radiation is known to take place in Casimir cavities. A Casimir cavity refers to any region in which electromagnetic modes are suppressed or restricted. When atoms enter into suitable micro Casimir cavities a decrease in the orbital energies of electrons in atoms will thus occur, with the effect being most pronounced for outer shell electrons. Such energy will be captured in the claimed devices. Upon emergence form such micro Casimir cavities the atoms will be re-energized by the ambient electromagnetic quantum vacuum. In this way energy is extracted locally and replenished globally from and by the electromagnetic quantum vacuum. This process may be repeated an unlimited number of times. This process is also consistent with the conservation of energy in that all usable energy does come at the expense of the energy content of the electromagnetic quantum vacuum. Two example variations of a system are disclosed that permit multiple extractions of electromagnetic quantum vacuum energy during passage of a gas through a series of micro Casimir cavities and that operate in a self-sustaining, recycling fashion. Similar effects may be produced by acting upon molecular bonds. The disclosed devices are scalable in size and energy output for applications ranging from replacements for small batteries to power plant sized generators of electricity. Since the electromagnetic quantum vacuum is thought to permeate the entire Universe, devices drawing power from the electromagnetic quantum vacuum in the fashion claimed will be effectively inexhaustible sources of power.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention may be understood by reference to the following detailed description taken in conjunction with the drawings briefly described below.

FIG. **1** is a diagrammatic illustration of a set of channels each containing a multiplicity of Casimir cavities in accordance with the present invention.

FIG. **2** is a diagrammatic illustration of a system for converting quantum vacuum energy into locally usable power in accordance with the present invention.

FIG. **3** is a diagrammatic illustration of a block of tunnels each containing a multiplicity of Casimir cavities in accordance with the present invention.

FIGS. **4A-4D** are diagrammatic illustrations of Casimir channels in bonded wafers in accordance with the present invention.

FIGS. **5**A-**5**C are diagrammatic illustrations of a device for oscillating a fluid though Casimir channels in accordance with the present invention.

FIGS. **6**A and **6**B are diagrammatic illustrations of a device switching the reflecting characteristics of walls of Casimir cavities in accordance with the present invention.

FIGS. **7**A and **7**B are diagrammatic illustrations of a device Casimir cavity wall spacing in accordance with the present invention.

FIG. **8** is a diagrammatic illustration of a device incorporating asymmetric Casimir cavity entry and exits in accordance with the present invention.

DETAILED DESCRIPTION

The first embodiments of this concept utilize Casimir cavities consisting of volumes through which, or in and out of which, gases flow, and which on the size scales of atoms appear as regions bounded by parallel plates of conducting material in which the plate scales are much larger than the plate separations; or by cylinders of conducting material in which the lengths of the cylinders are much larger than the diameters. It is claimed that other forms of Casimir cavity are capable of producing a similar effect, and the term Casimir cavity will be used to designate any volume capable of mode suppression of the zero-point field. The necessary condition is that the mode suppression ability of the Casimir cavity be matched to the electron energy levels in such a way as to result in a significant difference of the electron energy levels inside vs. outside the cavity.

These embodiments demonstrate the following concepts:

A method, comprising: (a) use of a device including a series of Casimir cavities and causing a specific gas to flow through the cavities, said Casimir cavities being configured and said specific gas being selected such that as the gas flows through the cavities energy is released from the gas; and (b) means for collecting at least some of said released gas.

A method, comprising: (a) providing a device including at least one Casimir cavity and causing a specific gas to enter and then exit the cavity, said Casimir cavity being configured and said specific gas being selected such that when the gas is caused to enter the cavity, energy is released from the gas; and (b) means for collecting at least some of said released energy.

A means for effecting changes in the electron configurations. A system for converting part of the energy of the electromagnetic quantum vacuum available at any point in the Universe to usable energy in the form of heat, electricity, mechanical energy or other forms of power.

A means for effecting changes in the electron configurations in the process of which energy is released.

A means for allowing the electron configurations to be re-energized by exposure to the ambient electromagnetic quantum vacuum radiation.

The use of microstructures consisting of many pairs of alternating Casimir cavities and regions in which the electromagnetic quantum vacuum radiation freely propagates.

The use of conducting strips on facing pairs of plates so that atoms go through alternating regions in which they are exposed to the full electromagnetic quantum vacuum spectrum, and regions in which part of the spectrum is blocked. The result is that they dump (or radiate) the energy difference into the local medium.

The use of spacers to separate the layer pairs.

The use of multiple conducting strips to amplify the effect (hugely).

The stacking of such plates with strips on both sides so that the top of one pair becomes the bottom of the next, each with identical conducting strips which form Casimir cavities with their partner strips in each pair.

The use of sandwiched layers of alternating conducting and non-conducting plates having micron sized thicknesses in which micron or submicron diameter holes are introduced by etching or some other method.

The stacking, co-registration and alignment of such sandwiched layers to produce many parallel Casimir tunnels having alternating Casimir and non-conducting segments.

The use of multiple segments to amplify the effect (hugely).

The use of monatomic gases as the medium in such a system.

The use of molecular gases in such a system for the purpose of modifying molecular bonds with the attendant release of energy.

A closed recycling system in which these processes take place.

Fabricatable and workable configuration and dimensions but with the claims not limited to these specific embodiments.

A means whereby the flow of gas is initiated and maintained in a closed system.

A means whereby the energy released from the electron orbital changes is converted into usable energy in the form of heat, electricity, mechanical energy or other forms of power.

Casimir Channels

This embodiment shown in FIG. **1** involves two square parallel plates **12** and **14**, 10×10 cm in size for illustration. On each one lay down 5000 conducting strips **16** that are 10 microns in width and the full 10 cm in length, separated by 10 microns non-conducting strips. Perpendicular to the strips deposit a spacer material **18** at 0.1 to 1 cm intervals with a height of 0.1 microns. Put the plates face to face and align the strips so as to form 5000 Casimir strips.

If we assume a gas flow rate of 10 cm/s parallel to the spacers and perpendicular to the strips, this would result in 1.3×10^{20} transitions/s.

An energy release of 1 to 10 eV per transition corresponds to 21 to 210 watts of energy release for the entire Casimir cavity. A stacked set of 10 or more such layers could be fabricated yielding 210 to 2100 watts for a 10×10×10 cm block.

This may be directly converted into electricity using a thermophotovoltaic process, or indirectly by using a heat exchanger. As in the previous embodiment, one means of capturing the emitted radiation is to surround the apparatus with a water bath.

The dimensions above are solely examples. The device may be scaled to both smaller and significantly larger dimensions.

The essential components of an energy generating device of this sort shown in FIG. **2** are:

(1) An array of parallel Casimir channels with conducting strips **10**

(2) A pump **22** providing continuous recycling of gas through the tunnels

(3) A means **24** for capturing the emitted energy

(4) A thermal photovoltaic, heat exchanger or other device **26** capable of converting output heat into electricity or other usable forms of power.

A desirable property of the system is its ability to radiate the accumulated energy locally and absorb it globally. Thus surprisingly the means **24** for capturing the emitted energy can capture the emitted energy without hindering the capture of the quantum vacuum energy by the gas. This is due to the fact that the vacuum field permeates all space and cannot be blocked. (Note that the reason that Casimir cavities have reduced vacuum energy modes is not that they block it, but rather that because of destructive interference they do not allow some of the electromagnetic modes to exist in their interior.) A second reason that the means **24** does not block the capture of the quantum vacuum energy is that the absorbed energy is dominantly shorter wavelength electromagnetic modes that are not absorbed by the means **24**, whereas the radiated energy can be longer wavelengths for which the means **24** has a much larger absorption coefficient. Such is the case, for example, when the means **24** comprises a water bath.

The first two components will be enclosed in sealed structure. The third and fourth components may be interior or exterior to this structure.

A variation on the above device consists of stacking plates such that the top of one pair becomes the bottom in the next pair, etc.

Casimir Tunnels

One embodiment of the concept shown in FIG. **3** is multiple, parallel, 0.1 micron diameter Casimir tunnels. If we let the length of the cylinder be 100 times the width, this results in z=10 microns for the length of the Casimir tunnel. We propose a segmented tunnel consisting of alternating conducting and non-conducting materials, each 10 microns in length. In a length of 1 cm, there could be 500 such pairs in segments, resulting in 500 energy releases events (each yielding 1 to 10 eV) for each transit of an atom through the entire 1 cm-long segmented Casimir tunnel.

Consider a one cubic cm "Casimir Block" that is built up of 10 micron thick alternating layers as shown in FIG. **3**. Assume that tunnels **32** of 0.1 micron diameter could be drilled through the cube perpendicular to the layers **34** (this is not physically possible, of course; tunnel manufacture must be done differently). Ten percent of the cross section comprises entrance to some 1.3 billion tunnels. The amount of energy released would be proportional to the flow rate of the gas through these tunnels.

A flow rate of 10 cm s^{-1} through a total cross sectional area of 0.1 cm^2 yields 1 cm^3 of gas per second flowing through the tunnels, which at STP would be 2.7×10^{19} atoms. A very simple sealed, closed-loop pumping system could maintain such a continuous gas flow. Since each atom interacts 500 times during its passage, there would be 1.3×10^{22} transitions per second in the entire cube of one cubic centimeter. An energy release of 1 to 10 eV per transition corresponds to 2150 to 21500 watts of energy release for the entire Casimir cube of segmented tunnels.

Obviously it is not possible to drill 1.3 billion tunnels having diameters of 0.1 microns. However it is feasible to use microchip technology to etch holes into the individual layers first and then assemble the stack. Extremely fine coregistration and alignment of stacks will need to be accomplished.

This may be directly converted into electricity using a thermophotovoltaic process, or indirectly by using a heat exchanger.

One means to capture the emitted energy is to surround the apparatus with a water bath. Water absorbs infrared radiation very effectively. For the wavelength range of 2 microns to 200 microns, the absorption coefficient of water is greater than 10 cm^{-1}. Therefore a layer of water that is 1 mm thick and surrounds the apparatus will be sufficient to absorb nearly all the emitted infrared radiation. The water will be heated, and that heat converted into the desired form of energy.

The dimensions above are solely examples. The device may be scaled to both smaller and significantly larger dimensions.

The essential components of an energy generating device of this sort are:

(1) An array of parallel segmented Casimir tunnels **32**

(2) A pump **22** providing continuous recycling of gas through the tunnels

(3) A means **24** for capturing the emitted energy

(4) A thermal photovoltaic, heat exchanger or other device **26** capable of converting output heat into electricity or other usable forms of power.

The first two components will be enclosed in sealed structure. The third and fourth components may be interior or exterior to this structure.

Casimir Channels in Bonded Wafers

The basic concept of the present invention is to flow gas into and out from multiple Casimir cavities. When the gas is outside of a Casimir cavity, a wide range of quantum mechanical vacuum electromagnetic modes are available to interact with the gas's atomic electronic orbital states. When the gas passes into a Casimir cavity the range of available modes is restricted and the gas sheds some of its electromagnetic energy such that this energy is available locally. When the gas once again flows out from the Casimir cavity, the gas's atomic electronic orbital state energy is recharged from quantum mechanical vacuum fields. Thus energy is harvested globally and delivered locally.

The configuration for a basic device comprising bonded wafers is shown in FIGS. **4**A-**4**D. A top view is shown in FIG. **4**. The device is 1 sq. cm. As seen from the south edge **41** in FIG. **4**B, it consists of two substrates **42** and **44** separated by a series of spacers which extend across the device from the south to the north side. These spacers have a height d, a width w_1, and a center-to-center spacing s_1. The thin gaps delineated by the spacers **48** extend to openings at the south edge of the device, as seen in FIG. **4**B and the north edge. As seen from the east edge in FIG. **4**C, the upper **44** and lower **42** substrates are each coated with conducting stripes **46** that extend from the east edge to the west edge. These stripes are discontinuous, such that the discontinuity occurs at each region where the stripe is intersected by a spacer **48**. These stripes have a width w_2 and a center-to-center spacing s_2. In the central region of the device there is a region of both substrates that has been removed to form a conduit **43** from close to the east edge to close to the west edge. This conduit does not extend all the way to the edges, but is instead sealed **45** at each end, as shown in FIG. **4**A. Finally, as seen in FIG. **4**D, which shows an east view of the central cross section, and in FIG. **4**A, a hole **47** extends through the upper substrate. This hole connects to the conduit **43** shown in FIGS. **4**A and **4**C. As can also be seen in FIGS. **4**A and **4**D, a connector ring **49** that surrounds the hole is affixed to the upper substrate.

For the device to function, gas tubing **28**, shown in FIG. **2**, is attached to the connector ring **49** extending from the upper substrate, forming a sealed connection. Pressurized gas flows through the tubing and the hole **47** in the upper substrate into the conduit **43** between the substrates. From the conduit **43** the gas flows from the central region through the gap between the substrates to the north and south edges. The spacers guide the gas so that it flows alternately between regions coated with the conducting stripes **46** and regions that are not coated with these stripes, until it reaches the north and south edges, at which point it escapes from the gap between the substrates. The escaped gas is captured in a surrounding enclosure, not shown, and pumped back through the tubing **28** into the hole at the top center of the device, forming a close-loop system. In this way the gas is passed through multiple Casimir cavities. The gas atoms or molecules absorb energy from the surrounding electromagnetic field when they are in the non-conducting region and then release a portion of their energy as they enter the gap between the conductive coatings, i.e., in the Casimir cavity.

The apparatus is surrounded by a means **24** to capture the released energy, such as a water bath, shown in FIG. **2**. Water absorbs infrared radiation very effectively. For the wavelength range of 2 microns to 200 microns, the absorption coefficient of water is greater than 10 cm^{-1}. Therefore a layer of water that is 1 mm thick and surrounds the apparatus is sufficient to absorb a large proportion of the emitted infrared radiation, providing thermal energy to heat the water. That energy can be used directly as heating source, or converted into the desired form of energy, by means **26** well known to those skilled in the art.

The materials and dimensions in the preferred embodiment are as follows. The upper **44** and lower **42** substrates are sapphire, which is transparent to much of the ambient electromagnetic spectrum, is thermally conductive, and is rigid and robust. The thickness of each substrate is 250 microns. The conducting regions **46** are formed by standard photolithography known to those skilled in the art. The width of each conducting stripe, w_2, is 2 microns, and separated by a 2 micron nonconducting region, to form a center-to-center spacing S_L of 4 microns. The stripe has gaps where the spacers **48** are to be formed. The conductive coating **46** is platinum, having a thickness of 40 nm. The spacers **48** consist of silicon dioxide, deposited and patterned by standard means known by those skilled in the art. The total spacer height, d, is 200 nm, its width, w_1, is 5 microns, and the center-to-center spacing, s_1, is 0.5 mm. The spacers are formed by depositing 100 nm thick layers on each substrate, and then joining them. The central conduit regions **43** are cut into the substrates using a standard diamond saw. The cuts are 100 microns in width and 50 microns in depth, forming a conduit that is approximately a 100 micron square. The hole **47** drilled through the upper substrate has a diameter of 1 mm, and is surrounded by a ring having a diameter of 2.5 mm. The ring **49** is affixed to the upper substrate by epoxy. The substrates are pressure bonded together by direct bonding (Plöl, 1999), with the bond forming between the silicon dioxide spacers layers on each substrate.

The steps in the device fabrication that are not described explicitly are well known to those skilled in the art.

Following the calculations presented in the background section, the power produced by a single such device is estimated to be between 1 and 10 watts for an input pressure of 8 atmospheres.

Pumping gas through the Casimir pores requires power. We examine how much power is required, as a check that it is not more than is produced by the device. Consider a Casimir block that contains 200 nm diameter pores over a 1 cm^2 area, having a thickness of 1 cm and a porosity of 0.25. We find the pressure and power required to produce a flux of 1 cm^3 per second at standard temperature and pressure (STP):

According to FIG. **10**(*a*) in a paper by Roy et al. (1993) a pressure drop of 760 torr (equal to one atmosphere) results from a flow of approximately 5 mol/m^2-s through a thickness of 60 microns, which corresponds to a gas velocity of 10 cm/s. Reducing the velocity by a factor of ten, making the appropriate unit conversions and multiplying the result by the thickness ratio of 1 cm (10^4 microns) divided by 60 microns gives the result that a pressure of 1700 Pa, corresponding to 17 atmospheres, is required to produce the desired gas flow. Multiplying this by the gas flux of 1 cm^3 s^{-1} results in a required power of 1.7 milliwatts. These results are only approximate, as temperature and structural variations through the Casimir pores are expected to produce resistance which will then require a somewhat greater pressure. In any case the required power of approximately 1.7 milliwatts is much lower than our estimate of 2.2 to 22 kilowatts of power release, and so much more power is produced than is used to produce the gas flow.

It is to be understood that the dimensions and materials can be varied greatly and still be part of this invention. The following is a list of some such variations, but it is far from exhaustive:

i. The substrates may be other insulating or partially conducting materials, such as silicon, glass, ceramic, plastic, etc.
ii. The conducting stripes can be formed of other conductors, such as copper, aluminum, gold, sliver, silicides, transparent conductors such as indium tin oxide, etc.
iii. Instead of depositing the stripes so that they protrude from the surface and potentially interfere with the gas flow, they may be recessed, either by etching recesses into which the conductors are deposited, or by using planarization techniques to coat an insulating layer between the stripes, using techniques well known in the industry.
iv. The spacer materials can be formed from polymers used, for example, as photoresist and electron-beam resist, from metals, and other materials.
v. Instead of depositing spacers they may be formed by the etching of one or both of the substrates to form grooves.
vi. The spacer height may be from 1 nm to many microns.
vii. The substrates may be bonded by pressure bonding or the use of adhesives, such as cyanoacrylics.
viii. The dimensions of the overall structure may be varied from the distance between a single pair of spacers and conductor/nonconductor region to large plates that are many meters in width.
ix. The individual devices may be sandwiched together to form thick structures. For example, in place of the 250 micron thick substrates, micro-sheet having a thickness of 50 microns or far less may be used so that dense structures are formed.
x. The working fluid may be a wide variety of gases, in addition to the noble gases described earlier, so that all mentions of gas atoms may be extended to molecules of various types.
xi. The working fluid may be a liquid, so that all mentions of gases and gas atoms may be extended to liquids of various types. For operation within approximately of 100° C., one possible liquid is ethylene glycol. For high temperature operation, the liquid can be sodium.

xii. Micro-motors formed using micro-electro-mechanical systems (MEMS) technology can be used to pump the gas through the channels.

xiii. The Casimir cavities may be composed of carbon nanotubes.

xiv. The pattern may be formed using self-assembled layers.

xv. The device may incorporate a naturally formed structure. For example, diatom shells (Goho, 2004a) consist of silicon dioxide patterned with features, including holes, that are tens of nanometers in size. They can be coated as needed with conductors to form Casimir cavities.

xvi. The water bath may be replaced with any other material or device that absorbs substantially the released energy wavelengths. Such materials include glass, organic polymers, thermophotovoltaic devices, among many possibilities known to those skilled in the art.

xvii. Rather than surrounding the entire apparatus, the absorbing material may be placed in the apparatus, for example coating the channels through which the gas flows. Such placement can allow the absorber to reside within roughly an emission wavelength of the gas that is releasing the energy.

Gas Oscillating Through Casimir Channels

The device described in the previous embodiment exposes the gas atoms to a very large number of transitions between Casimir cavity regions (between conducting layers) and exposed regions (without the conducting layers) by pumping them across multiple transitions. Instead of pumping gas through the device, gas atoms can simply be oscillated back and forth between Casimir cavity and exposed regions.

A simple way to visualize this, but not necessarily the most efficient working device, is to consider the device of FIGS. **4**A-**4**D, but with the gaps sealed at the north and south edges. Instead of connecting to tubing via the connector ring, the ring is sealed with a thin metal diaphragm. Before sealing the device it is filled with the desired working gas. An ultrasonic transducer is then mated to the diaphragm. When the ultrasonic transducer is powered, it rapidly compresses and decompressed the gas, causing it to oscillate back and forth between Casimir and exposed regions.

A vertical oscillatory flow device is shown in FIGS. **5**A-**5**C. FIG. **5**A shows a top view, in which many small holes **54** are formed in the substrate surface. The device is surrounded by a connector ring **58**. A magnified cross section of the holes is shown in FIG. **5**B. The holes **54** have a diameter d, a center-to-center spacing s, a depth t_2, and the thickness of a conducting region **56** at the surface is t_1. A central cross section of the entire device is shown in FIG. **5**C. It shows the substrate (holes and conducting layer not shown), the connector ring at the periphery, and a thin diaphragm **57** attached to the top of the connector ring.

The gap and holes are filled with the chosen working gas **59**. An ultrasonic transducer or other source of high frequency vibrations is placed in contact with the diaphragm **57** and powered. This produces gas pressure oscillations that force gas atoms past the Casimir region **55** formed at the top of each hole, alternately in upward and downward directions. Instead of a single conducting layer at the top, multiple alternating conducting and non-conducting layers can be formed at the top of the holes, to multiply the effect. As in the embodiment of FIGS. **4**A-**4**D, the apparatus is surrounded by a means for absorbing the released energy, such as a water bath **24**.

The device is fabricated as follows. The conducting layer **56** is deposited using vacuum deposition, such as sputtering, or from a liquid by anodic or electroless deposition. The layers are patterned by methods known to those skilled in the art, such as electron-beam lithography or photolithography. Alternatively, the holes **54** can be formed using self-assembled monolayers to create the lithography mask, as known to those skilled in the art. The holes are etched to a high aspect ratio, e.g., ratio of depth-to-diameter of 20, such as by ion milling. The outer ring **58** is attached using epoxy, the region is filled with the desired working gas **59**, and the diaphragm **57** is attached with epoxy.

The materials and dimensions in the preferred embodiment are as follows. The substrate **52** is sapphire, and has diameter of 2.54 cm and a thickness of 250 microns. The conducting layer **56** is aluminum, of thickness t_1 of 1 micron. The hole **54** depth t_2 is 4 microns. The hole diameter d is 0.2 microns and center-to-center spacing s is 0.3 microns.

It is to be understood that the shape, dimensions, modulation techniques and materials can be varied greatly and still be part of this invention. The following is a list of some such variations, but it is far from exhaustive:

i. The Casimir cavities may be composed of carbon nanotubes.

ii. The working fluid may be a wide variety of gases, in addition to the noble gases described earlier, so that all mentions of gas atoms may be extended to molecules of various types.

iii. The working fluid may be a liquid, so that all mentions of gases and gas atoms may be extended to liquids of various types. For operation of up to approximately 100° C., one possible liquid is ethylene glycol. For high temperature operation, the liquid can be sodium.

iv. Instead of actively causing the gas atoms to oscillate into and out from the Casimir cavity regions, the oscillations can result from ambient thermal vibrations (e.g., Brownian motion).

v. The configuration of the device can be similar to that of the MEMS device of FIGS. **7**A and **7**B (described as part of a later embodiment), such that the working gas is pushed back and forth between the left-hand and right-hand regions.

vi. The pattern may be formed using self-assembled layers.

vii. The device may incorporate a naturally formed structure. For example, diatom shells consist of silicon dioxide patterned with features, including holes, that are tens of nanometers in size. They can be coated as needed with conductors to form Casimir cavities.

viii. The pumping can be driven by a naturally occurring mechanism. For example, some yeast cell have been found to naturally vibrate at 1.6 kHz (Goho, 2004b). This could be used to cause a gas to oscillate back and forth between Casimir cavity and exposed regions.

ix. The water bath may be replaced with any other material or device that absorbs substantially the released energy wavelengths. Such materials include glass, organic polymers, thermophotovoltaic devices, among many possibilities known to those skilled in the art.

x. Rather than surrounding the entire apparatus, the absorbing material may be placed in the apparatus, for example coating the channels through which the gas flows. Such placement can allow the absorber to reside within roughly an emission wavelength of the gas that is releasing the energy.

Casimir Cavities in Flexible Polymer

Rather than moving the working gas by flowing it (FIGS. **4**A-**4**D) or vibrating it into and out of a Casimir cavity (FIGS. **5**A-**5**C), the cavity wall characteristics can be switched, which results in a shift in the cavity's allowed modes. This produces the same result of tapping vacuum electromagnetic energy that the flowing gas device of the embodiment of FIGS. **4**A-**4**D produces. One way to accomplish this is to put the working gas into gaps formed in flexible photonic crystals. A photonic crystal blocks and passes bands of electromagnetic radiation, where the band wavelength ranges depend upon the material properties and spacing of small repeated structures. A flexible photonic crystal can be formed by embedding an array or rigid objects, such as silicon pillars, in a thin film of flexible polymer. The electromagnetic (or optical) properties of such two-dimensional slab photonic crystal structures is well known to those skilled in the art (Park, 2002).

FIGS. **6**A and **6**B show such a photonic crystal device. FIG. **6**A is a top view, showing metal supports **62** at both ends of a polymer film **64**. The rigid pillars that form the phonic crystal are buried in the polymer. As the film is stretched in the plane of the paper, the pillar spacing in the plane normal to the paper is decreased, which changes the electromagnetic passband. FIG. **6**B is an edge view showing the supports **62**, the polymer film **64**, and gaps in the film that are filled with the working gas **69**. (For clarity, the pillars are not shown.) The gap size is sufficiently narrow to produce a significant Casimir effect, e.g., 200 nm. The length or width need to be sufficiently small to maintain the narrow gap, e.g., 1 micron. The stretching takes place by attaching one support to a stationary object and attaching the other support to a vibrator, such as a piezoelectric crystal, which itself may be attached on its opposing side to another stationary support. As in the embodiment of FIGS. **4**A-**5**D, the apparatus is surrounded by a means for absorbing the released energy, such as a water bath **24**.

It is to be understood that the shape, dimensions, modulation techniques and materials can be varied greatly and still be part of this invention. The following is a list of some such variations, but it is far from exhaustive:

i. Instead of stretching the polymer, it can be modulated with an acoustic signal through the air, or through a liquid that surrounds it.

ii. Instead of stretching the polymer, it can be modulated with an ambient thermal vibrations. As the working gas and the structure heats up, the vibrations increase.

iii. The polymer embedded with rigid pillars may be formed into small spheres that are filled with the working gas. These spheres can fill or partially fill a volume in which the pressure is modulated, either by enclosing the volume and modulating the pressure in the entire volume, by passing an acoustic signal through the volume, or by thermal vibrations. This modulation causes the passband of the photonic crystal that surrounds the working gas to vary. Although the shape of the device is substantially different from that of FIGS. **6**A-**6**B, the function is the same.

iv. The working fluid may be a wide variety of gases, in addition to the noble gases described earlier, so that all mentions of gas atoms may be extended to molecules of various types.

v. The working fluid may be a liquid, so that all mentions of gases and gas atoms may be extended to liquids of various types. For operation of up to approximately 100° C., one possible liquid is ethylene glycol. For high temperature operation, the liquid can be sodium.

vi. The water bath may be replaced with any other material or device that absorbs substantially the released energy wavelengths. Such materials include glass, organic polymers, thermophotovoltaic devices, among many possibilities known to those skilled in the art.

vii. Rather than surrounding the entire apparatus, the absorbing material may be placed in the apparatus, for example in the polymer film through which the gas flows. Such placement can allow the absorber to reside within roughly an emission wavelength of the gas that is releasing the energy.

Modulating Casimir Cavity Wall Spacing

Rather than moving the working gas by flowing it (FIGS. **4**A-**4**D), vibrating it into and out of a Casimir cavity (FIGS. **5**A-**5**C), or switching the characteristics of walls of the cavity to change the passbands (FIGS. **6**A and **6**B), the spacing between the cavity walls can be modulated. This produces the same result of tapping zero point energy that the flowing gas device of the previous embodiments produce. One way to accomplish this is to put the working gas into gaps formed in micro-electro-mechanical systems (MEMS).

MEMS technology makes use of semiconductor lithography techniques to build miniature mechanical devices. The Casimir effect has already been found to be in evidence in MEMS devices. In 2001, Chan and co-workers at Bell Labs Lucent Technologies first demonstrated the effect of the Casimir force in a MEMS device. A gold coated sphere was brought close to a MEMS seesaw paddle, consisting of a polysilicon plate suspended above a substrate on thin torsion rods. The Bell Labs researchers demonstrated the effect of the Casimir force in rocking the plate.

In the current invention we make use of MEMS technology to modulate the spacing between Casimir cavity walls. (Note that we are not making use of the Casimir force to change this spacing, as was done in the Bell Labs demonstration.) The basic MEMS device used to accomplish this is shown in FIGS. **7**A and **7**B. A side view is shown in FIG. **7**A. Two conducting electrodes **76** are shown on the substrate. A pivoting polysilicon plate **74** is shown suspended above the substrate **72**. A conducting layer **77** is formed on the underside of this plate. A top view is shown in FIG. **7**B. The pivoting plate **74** forms the central rectangular region, which is surrounded by a gap **73**. The pivoting arm **75** connects this plate to the surrounding region at the top and bottom of the rectangle. As in the earlier embodiments, the apparatus is surrounded by a means **24** for absorbing the released energy, such as a water bath

The device functions as follows. The working gas fills the region between the pivoting plate **74** and the substrate **72**. A voltage is applied first between the pivoting plate and the left-hand electrode. This causes the distance between the left side of the plate and the substrate to diminish, thereby changing the dimensions of the Casimir cavity formed by these two surfaces. Then the voltage is instead applied between the pivoting plate and the right-hand electrode. This causes the plate to pivot, such that the distance between the right side of the plate and the substrate diminishes, thereby changing the dimensions of the Casimir cavity formed by these two surfaces. The voltage is switched alternately between these two electrodes, causing the plate to oscillate back and forth. The oscillating action is greatly enhanced by the torsion of the pivots, so that very little energy is required to maintain the oscillation.

The techniques to fabricate such a MEMS device is well known to those skilled in the art.

It is to be understood that the shape, dimensions, modulation techniques and materials can be varied greatly and still be part of this invention. The following is a list of some such variations, but it is far from exhaustive:

i. Instead of using a MEMS device, the Casimir cavity can be formed between a substrate and a suspended conducting sheet. A similar technology has been used to form electrostatic acoustic speakers, albeit with larger spacings.

ii. Gaps can be formed in a polymer, with both sides of the gap coated with a conductor and the gap filled with a working gas. The polymer can then be stretched, as in the embodiment of FIGS. **6**A and **6**B, such that the spacing of the Casimir cavity formed by the two conductors is modulated. A figure of this would appear much like that depicted in FIG. **6**B

viii. Instead of stretching the polymer, it can be modulated with an acoustic signal through the air, or through a liquid that surrounds it.

ix. Instead of stretching the polymer, it can be modulated with an ambient thermal vibrations. As the working gas and the structure heat up, the vibrations will increase.

x. The polymer coated on its interior surface with a conductor may be formed into small spheres that are filled with the working gas. These spheres can fill a volume in which the pressure is modulated, either by enclosing the volume and modulating the pressure in the entire volume, by passing an acoustic signal through the volume, or by thermal vibrations. This modulation causes the spacing of the Casimir cavity in which the working gas is contained to vary. Although the shape of the device is substantially different from that of FIGS. **7**A and **7**B, the function is the same.

xi. The working fluid may be a wide variety of gases, in addition to the noble gases described earlier, so that all mentions of gas atoms may be extended to molecules of various types.

xii. The working fluid may be a liquid, so that all mentions of gases and gas atoms may be extended to liquids of various types. For operation of up to approximately 100° C., one possible liquid is ethylene glycol. For high temperature operation, the liquid can be sodium.

xiii. The water bath may be replaced with any other material or device that absorbs substantially the released energy wavelengths. Such materials include glass, organic polymers, thermophotovoltaic devices, among many possibilities known to those skilled in the art.

xiv. Rather than surrounding the entire apparatus, the absorbing material may be placed in the apparatus, for example coating the substrate and cap of the region containing the gas. Such placement can allow the absorber to reside within roughly an emission wavelength of the gas that is releasing the energy.

We note that the MEMS device of FIGS. **7**A and **7**B can also be used to move the working gas back and forth between the left-hand and right-hand regions. This function is consistent with the embodiment of FIGS. **5**A-**5**C, in which the working gas is vibrated into and out of a Casimir cavity.

Assymetric Casimir Cavity Entry and Exits Including Absorbing Means

As a prelude to this embodiment, we review the processes involved in the present invention. A general concept of this entire invention is that a gas that is in equilibrium with the ambient electromagnetic modes, which include the vacuum field (also known as the zero point field), is caused to enter a Casimir cavity. For the purposes of this entire invention a Casimir cavity is defined as any region in which the electromagnetic modes are restricted. Upon approaching this region, the electromagnetic modes that the space supports are restricted and the energy of the electron orbitals of the gas atoms is reduced. As a consequence of this reduction the excess energy is emitted and absorbed by the apparatus, providing heat energy. By the time the atoms are in the Casimir cavity, nearly all the excess energy has been radiated (unless the gas flow is extremely fast). The gas atoms pass through the Casimir cavity, and upon emerging from this region to a region that supports a broader range of electromagnetic modes, the energy of the electron orbitals of the gas atoms is again allowed to rise to its previous value. The compensation for the energy deficit is provided from the ambient electromagnetic modes.

One of the tenets of the current invention is that excess energy released when the gas approaches the Casimir cavity is delivered locally and that the energy deficit that must be compensated for when it emerges from the cavity is supplied from global sources. In this way the ambient electromagnetic field is tapped to provide usable energy. There may be conditions in which it is possible that the excess energy release and the deficit energy supply are both local, in which case no net energy is provided. Similarly, there may be conditions in which it is possible that the excess energy release and the deficit energy supply are both global, in which case again no net energy is provided. To avoid these possibilities, we provide an asymmetry in the apparatus to ensure that the excess energy is released locally and that the energy deficit is supplied globally.

The concept of embodiment is shown in FIG. **8**. This figure depicts a channel **88**, similar to that shown in some of the earlier embodiments. Gas is constricted between two substrates **82** and **83** and flows through the channel in the direction of the arrows. As in the previous cases, gas flows from a region in which the substrate is not coated **87** with a conducting layer to a region in which it is **86**. The difference here is that an intermediate region **84** is provided in which the substrates are coated with an absorbing layer. This absorbing region absorbs the excess energy that is radiated from the atoms as they approach the Casimir cavity (conducting) region. The absorbing region is not substantially conducting, and therefore does not substantially restrict the electromagnetic modes that are supported in the region. Upon exiting the Casimir cavity (conducting) region, the atoms pass immediately into another region with no absorbing region **87**. Thus upon approaching the Casimir cavity the atoms are forced to deliver their excess energy locally because it is absorbed by the absorbing region **87**. Upon emerging from the Casimir cavity the gas atoms are forced to supply their energy deficit non-locally, i.e., globally, because there is no local source for this energy.

As an option, a further aspect of this invention is to situate the absorbing region within roughly one emission wavelength of the gas atoms at the time that they are emitting. No such layer is provided within such a distance when the gas atoms emerge from the Casmir cavity and are supplied with energy. The substrate is chosen such that it does not absorb the emission wavelengths.

The absorbing layers may comprise glass (amorphous silicon dioxide, usually with impurities), and the substrate may comprise sapphire. The glass has a much broader absorption band in the far infrared than does the sapphire. A wide range of other materials may be provided to form the absorbing layers and non-absorbing or less absorbing substrate. Such materials are known to those skilled in the art, and are available in tables and handbooks.

The sequence of regions depicted in FIG. **8** may be repeated to form the sort of multiply striped structure described in the embodiment of FIGS. **4**A-**4**D.

The dimensions of the channel and the apparatus are approximately the same as those of embodiment of FIGS. **4**A-**4**D. Similarly the attachments to provide for gas flow, the spacers, and other aspects of the apparatus are similar to those described in embodiment of FIGS. **4**A-**4**D. The conducting layer length is chosen so that the emerging atoms do not have substantial access to radiation emitted from the absorbing regions. Note that, unlike embodiment of FIG. **2**, it is not necessary to surround the apparatus with a means for absorbing the released energy **24**, such as a water bath.

The device fabrication is not described explicitly as it is well known to those skilled in the art.

It is to be understood that the dimensions and materials can be varied greatly and still be part of this invention. The following is a list of some such variations, but it is far from exhaustive:

i. The substrates may be other insulating or partially conducting materials, such as silicon, glass, ceramic, plastic, etc.

ii. The conducting stripes can be formed of other conductors, such as copper, aluminum, gold, sliver, silicides, transparent conductors such as indium tin oxide, etc.

iii. The stripes may be recessed in the substrate or they protrude from the surface.

iv. The individual devices may be sandwiched together to form thick structures. For example, in place of the 250 micron thick substrates, micro-sheet having a thickness of 50 microns or far less may be used so that dense structures are formed.

v. The working fluid may be a wide variety of gases, in addition to the noble gases described earlier, so that all mentions of gas atoms may be extended to molecules of various types.

vi. The working fluid may be a liquid, so that all mentions of gases and gas atoms may be extended to liquids of various types. For operation within approximately of 100° C., one possible liquid is ethylene glycol. For high temperature operation, the liquid can be sodium.

vii. Micro-motors formed using micro-electro-mechanical systems (MEMS) technology can be used to pump the gas through the channels.

viii. The Casimir cavities may be composed of carbon nanotubes.

ix. The pattern may be formed using self-assembled layers.

The device may incorporate a naturally formed structure. For example, diatom shells consisting of silicon dioxide patterned with features, including holes, that are tens of nanometers in size. To the extent necessary, these can be coated as needed with conductors to form Casimir cavities.

What is claimed is:

1. A system for extracting and collecting electromagnetic radiation from the ambient surroundings, comprising:

(a) a supply of fluid characterized by its ability to (i) take in electromagnetic radiation from the ambient surroundings and (ii) release at least some of said energy when the fluid is caused to pass into a Casimir cavity;

(b) a first arrangement configured to collect at least some of the electromagnetic radiation released by said fluid;

(c) a second arrangement including means defining a given path for containing said fluid along said path;

(d) a third arrangement including a Casimir cavity positioned within said given path and cooperating with said second arrangement such that said fluid is caused to pass into and out of the cavity as the fluid is contained along said given path, said Casimir cavity being positioned in sufficient communication with the ambient surroundings and with said first arrangement so as to (i) cause said fluid containing electromagnetic energy taken from the ambient surroundings to release at least some of said energy to said first arrangement when the fluid passes into said cavity and (ii) to again take in electromagnetic energy from the ambient surroundings when the fluid passes out of said cavity.

2. A system according to claim **1** wherein said second arrangement is configured such that said fluid is caused to flow along said path into and out of said Casimir cavity.

3. A system according to claim **1** wherein said second and third arrangements are configured such that said Casimir cavity is caused to move with respect to said fluid such that the fluid is in turn caused to pass into and out of said Casimir cavity.

4. A system according to claim **3** wherein said third arrangements configured so as to cause said Casimir cavity to move back and forth between first and second spaced apart positions.

5. A system according to claim **1** wherein said means defining said given path defines a closed passageway for containing said fluid and wherein said second arrangement is configured such that the same fluid is caused to cycle into and out of said Casimir cavity.

6. A system according to claim **5** wherein said passageway defines a looped path and wherein said second arrangement includes a mechanism configured to cause said fluid to flow around said path through said passageway into and out of said Casimir cavity.

7. A system according to claim **5** wherein said second arrangement includes a mechanism for causing said fluid to flow back and forth through said passageway into and out of said Casimir cavity.

8. A system according to claim **7** wherein said absorbing material is a liquid.

9. A system according to claim **8** wherein said liquid material is water.

10. A system according to claim **1** wherein said fluid is a gas.

11. A system according to claim **10** wherein said gas is a monatomic gas.

12. A system according to claim **10** wherein said gas is a molecular gas.

13. A system according to claim **1** wherein said first arrangement includes a container of material for absorbing electromagnetic energy, said absorbing material surrounding at least said Casimir cavity.

14. A system according to claim **1** wherein said Casimir cavity includes opposing walls and wherein said third arrangement is configured so as to cause the position of said Casimir cavity walls to move back and forth between first and second spaced positions.

15. A system for extracting and collecting electromagnetic energy from the ambient electromagnetic quantum vacuum, comprising:

(a) a first arrangement defining at least one Casimir cavity configured to cause gas containing electromagnetic energy obtained from the ambient electromagnetic quantum vacuum to release at least some of said energy when said gas is passed into said cavity;

(b) a second arrangement located in the ambient electromagnetic quantum vacuum and including a source of said gas and a mechanism cooperating with said first arrangement so as to cause said gas to pass from the ambient electromagnetic quantum vacuum into said Casimir cavity and then out of said cavity and back into the ambient electromagnetic quantum vacuum, whereby the gas when passing into said Casimir cavity releases at least some of its energy and then, upon passing back into the ambient electromagnetic quantum vacuum, again takes in electromagnetic energy from the ambient electromagnetic quantum vacuum, said means and said first arrangement cooperating with one another such that said fluid passes into and out of said Casimir cavity by relative movement between the cavity and gas; and

(c) a third arrangement for capturing at least some of the electromagnetic energy released by said fluid, said third arrangement including means located in a position with respect to said Casimir cavity such that at least some of the electromagnetic energy released by said gas is captured by said absorber.

16. A system, comprising:

(a) a first arrangement including a number of Casimir cavities, each of which is configured to cause fluid containing electromagnetic energy obtained from the ambient surroundings to release at least some of said energy when said fluid is passed into said cavity;

(b) a second arrangement located in the ambient surroundings and including a source of said fluid and means cooperating with said first arrangement for causing said fluid to pass from the ambient surroundings into each of said Casimir cavities and then out of the cavity and back into the ambient surroundings, whereby the fluid when passing into said Casimir cavities releases at least some of its energy and then, upon passing back into the ambient surroundings, again takes in electromagnetic energy from the ambient surroundings, said means and said first arrangement cooperating with one another such that said fluid passes into and out of said Casimir cavities by relative movement between the cavities and fluid; and

(c) a third arrangement for capturing at least some of the electromagnetic energy released by said fluid.

17. A system according to claim **16** wherein said means includes at least one fluid passageway extending from the ambient surroundings into and though said Casimir cavities and back into the ambient surroundings and wherein said Casimir cavities are defined by a series of conducting strips located within said passageway, said series of conducting strips including a first group of spaced apart strips located on one side of the passageway and a second groups of spaced apart strips on a opposite side of said passageway in alignment with respective strips of said first group, each of said aligned pair of strips being positioned relative to one another to produce a Casimir cavity.

18. A method, comprising:

(a) providing a first arrangement defining at least one Casimir cavity configured to cause fluid containing electromagnetic energy obtained from the ambient surroundings to release at least some of said energy when said fluid is passed into said cavity;

(b) providing a source of said fluid;

(c) causing said fluid to pass from the ambient surroundings into said Casimir cavity and then out of said cavity and back into the ambient surroundings such that the fluid when passing into said Casimir cavity releases at least some of its energy and then, upon passing back into the ambient surroundings, again takes in electromagnetic energy from the ambient surroundings, said fluid being cause to pass into and out of said Casimir cavity by relative movement between the cavity and fluid; and

(c) capturing at least some of the electromagnetic energy released by said fluid.

19. A method of extracting and collecting electromagnetic radiation from the ambient surroundings, comprising:

(a) providing a supply of fluid characterized by its ability to (i) take in electromagnetic radiation from the ambient surroundings and (ii) release at least some of said energy when the fluid is caused to pass into a Casimir cavity;

(b) providing a first arrangement configured to collect at least some of the electromagnetic radiation released by said fluid;

(c) providing a second arrangement including means defining a given path for containing said fluid along said path;

(d) providing a third arrangement including a Casimir cavity positioned within said given path;

(e) causing said fluid to pass into and out of the cavity as the fluid is contained along said given path; and

(f) positioning said Casimir cavity in sufficient communication with the ambient surroundings and with said first arrangement so as to (i) cause said fluid containing electromagnetic energy taken from the ambient surroundings to release at least some of said energy to said first arrangement when the fluid passes into said cavity and (ii) to again take in electromagnetic energy from the ambient surroundings when the fluid passes out of said cavity.

20. A system, comprising:

(a) a first arrangement defining at least one mechanism designed to cause the atoms and molecules making up a given fluid containing electromagnetic energy obtained from the ambient surroundings to change in configuration in a way which releases at least some of said energy when said fluid is passed into said mechanism;

(b) a second arrangement located in the ambient surroundings and including a source of said fluid and means cooperating with said first arrangement for causing said fluid to pass from the ambient surroundings into said mechanism and then out of said mechanism and back into the ambient surroundings, whereby the fluid when passing into said mechanism releases at least some of its energy and then, upon passing back into the ambient surroundings, again takes in electromagnetic energy from the ambient surroundings, said means and said first arrangement cooperating with one another such that said fluid passes into and out of said mechanism by relative movement between the mechanism and fluid; and

(c) a third arrangement for capturing at least some of the electromagnetic energy released by said fluid.

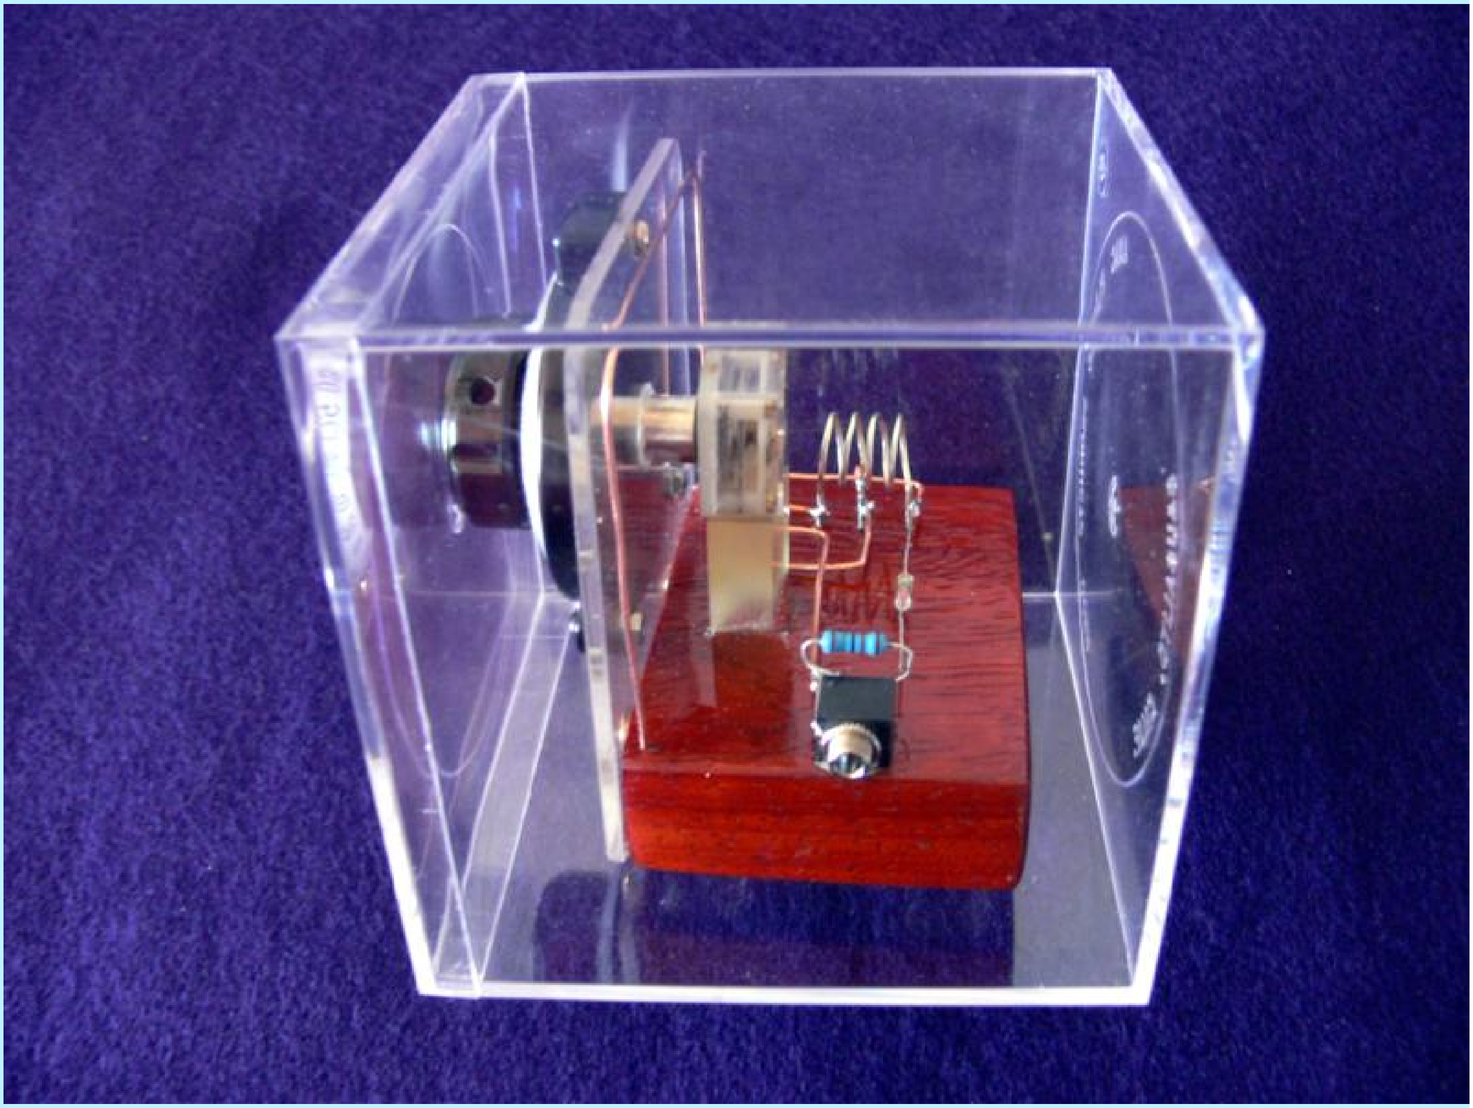
FM Crystal Radios?

copyright © 2006 by Larry J Solomon

I have heard, even from a physicist, that it is impossible to build FM crystal radios. On the other hand some experimenters claim that they have built them. This argument intrigued me to try and build an FM crystal radio, which I have done successfully. To my surprise, the result is an astounding performer, pulling in four local stations in Tucson. When connected as a receiver to a good sound system the sound fidelity is as good or better than more expensive AM radios. In fact, it sounds "high-fidelity".



This picture shows the Solomon FM Crystal Set in an acrylic display case. I made the set specifically to fit inside this case (the case came first).

My definition of a crystal radio is one that is not powered, except by the radio transmission itself and employs a crystal detector. So, it should work without any batteries or AC power. An FM crystal receiver must be able to detect and receive FM signals well enough to be heard in earphones without any such extra power.

This FM receiver is an amazing performer. It has crystal clear reception (pun intended), good sensitivity, but only fair selectivity. This set was a discovery for me. I started out by designing and building the normal AM sets. Then one day while testing the "Mystery" set (see my other web links), to my surprise, in addition to the expected panoply of AM stations, I heard a very faint signal that I could not tune out. At first, it seemed too weak to identify. When I tuned out all the AM stations, I was astonished to hear the announcement "KiiM FM, 99.5"! This is a

country music FM station here in Tucson. It was all over the dial, untunable, but the much louder AM signals masked it when they were tuned in.

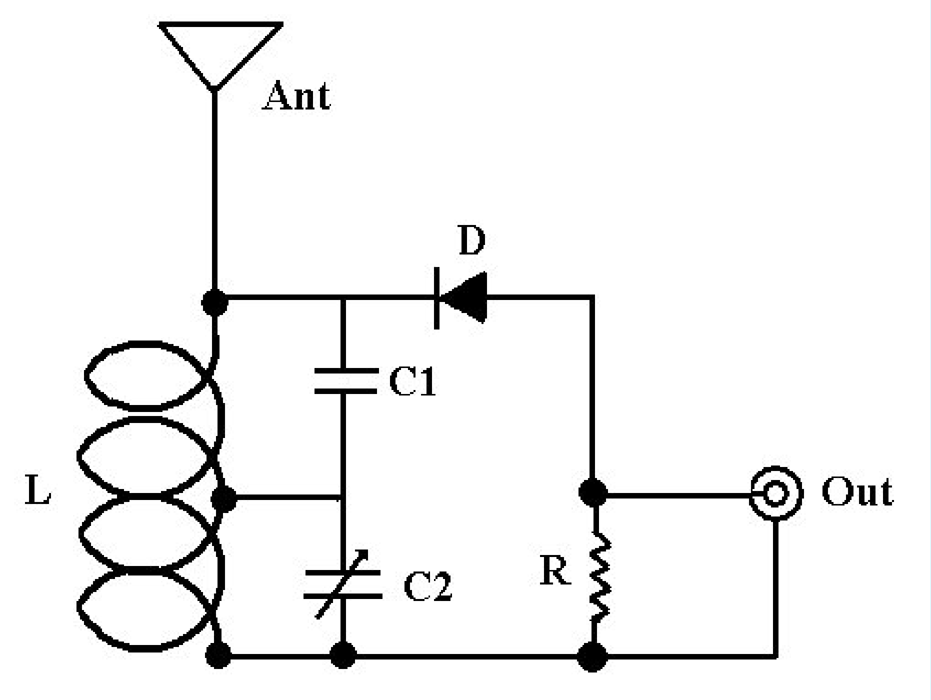
I set myself the task of trying to improve the FM reception. I tried some simple circuit modifications that did not seem to improve anything. Then I connected a dipole antenna instead of the AM antenna I normally use. Suddenly, the FM signal was much clearer, although still weak. By using the audio output and sound system amplifier, I was even more amazed that four different FM stations came in loud (or rather medium) and clear. I found that changing the telescoping antenna length and position I could tune the stations in and out. They were KRQ, KLPX, KiiM, and KHYT all local FM stations with transmitters nearby. Their reception was also affected by the length and position of the audio output cable.

After doing some research, I discovered that there was a physical theory that claimed that FM reception was possible and even probable using the same circuit as an AM receiver. The theory is called "slope detection". So, I set out to find circuit improvements. A web search yielded little, mostly theory. But there was enough information that I thought I could make some modifications to the AM circuits to make them more tunable to FM signals and less tunable to AM. Since FM operates at higher frequencies, all I had to do, I thought, was make the coil and caps smaller. After much "tinkering" I arrived at the current circuit.

The circuit looks identical to a classic AM crystal circuit but is even simpler to build. The components were reduced in dimension to resonate at higher frequencies. This was done by experimenting with smaller and smaller coils and capacitors. The antenna is also much reduced in size (from that of AM) to resonate at higher frequencies (the antenna is crucial). The air variable capacitor I used has two trimmers in it which should be adjusted for best reception.I have found that a commonly available vernier dial and knob will fit the capacitor nicely. See end of article for a picture of the variable. C3 is a ceramic capacitor of 18 pf, but may be anywhere from 10 to 50pf. A detected FM signal is converted to AM due to an effect called slope detection that modulates amplitude.

This FM Crystal Set works best near the transmitter (I have not tested it beyond about 10 miles). Secondly, the sound level is quiet, especially without an amplifier. A quiet room is needed for listening with earphones. One must be willing to move the set around to find a location for the best reception of signals. However, in addition to listening with high impedance earphones (crystal or otherwise), the set can be connected directly to an audio amplifier's low level magnetic input which can then play amplified through a sound system at any volume -- sounds GREAT. In fact, I recommend starting tests with the FM crystal set by connecting it to the low-level phono inputs of a receiver or preamplifier. (Nowadays, many receivers don't even have a phono input!) That way you can crank up the volume, which makes it more likely to find the FM stations. If no signals are detected, I also recommend connecting an external "rabbit ear" antenna or hanging a short wire (12 inches or so) in various positions next to the internal antenna. The variable length of rabbitt ears can help to tune in stations.

No additional wiring or antenna is necessary (the antenna is optimized in length for FM.)

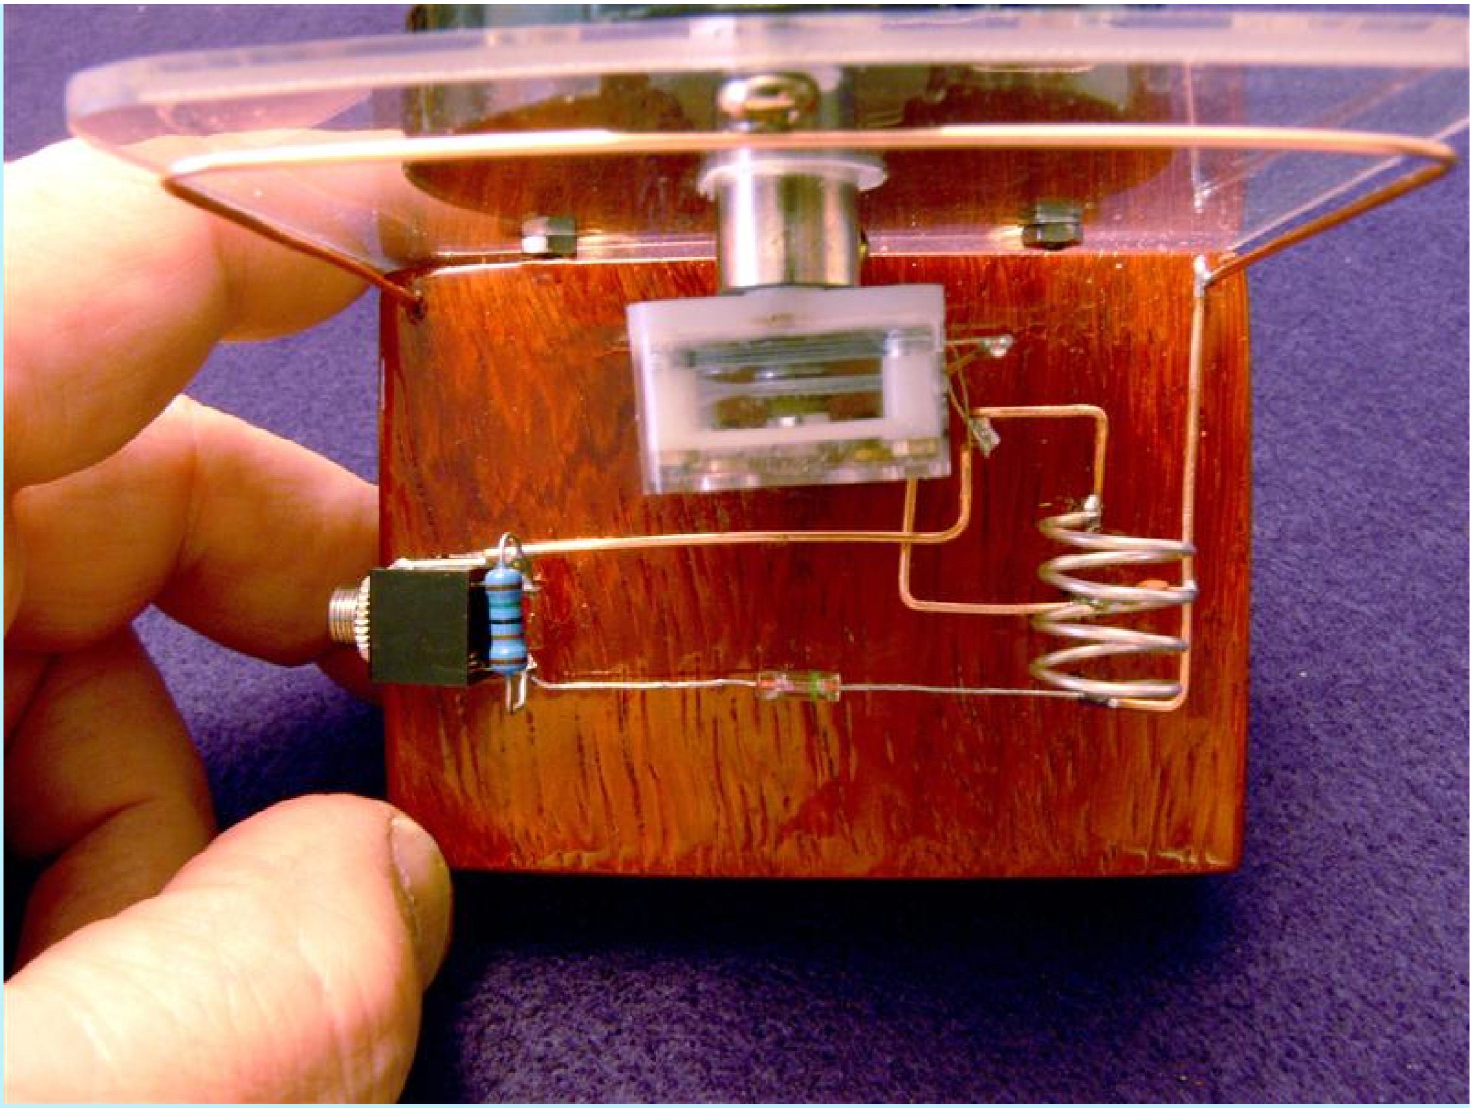


L - 4 turns #18 copper or silver wire, 12mm inside diameter, tapped at 2.5 turns
Ant - 7 inches of #18 bare copper wire
C1 - 18 pf ceramic capacitor
C2 - 50 pf air variable capacitor
D - 1N34 diode or rock crystal
R - 150K resistor

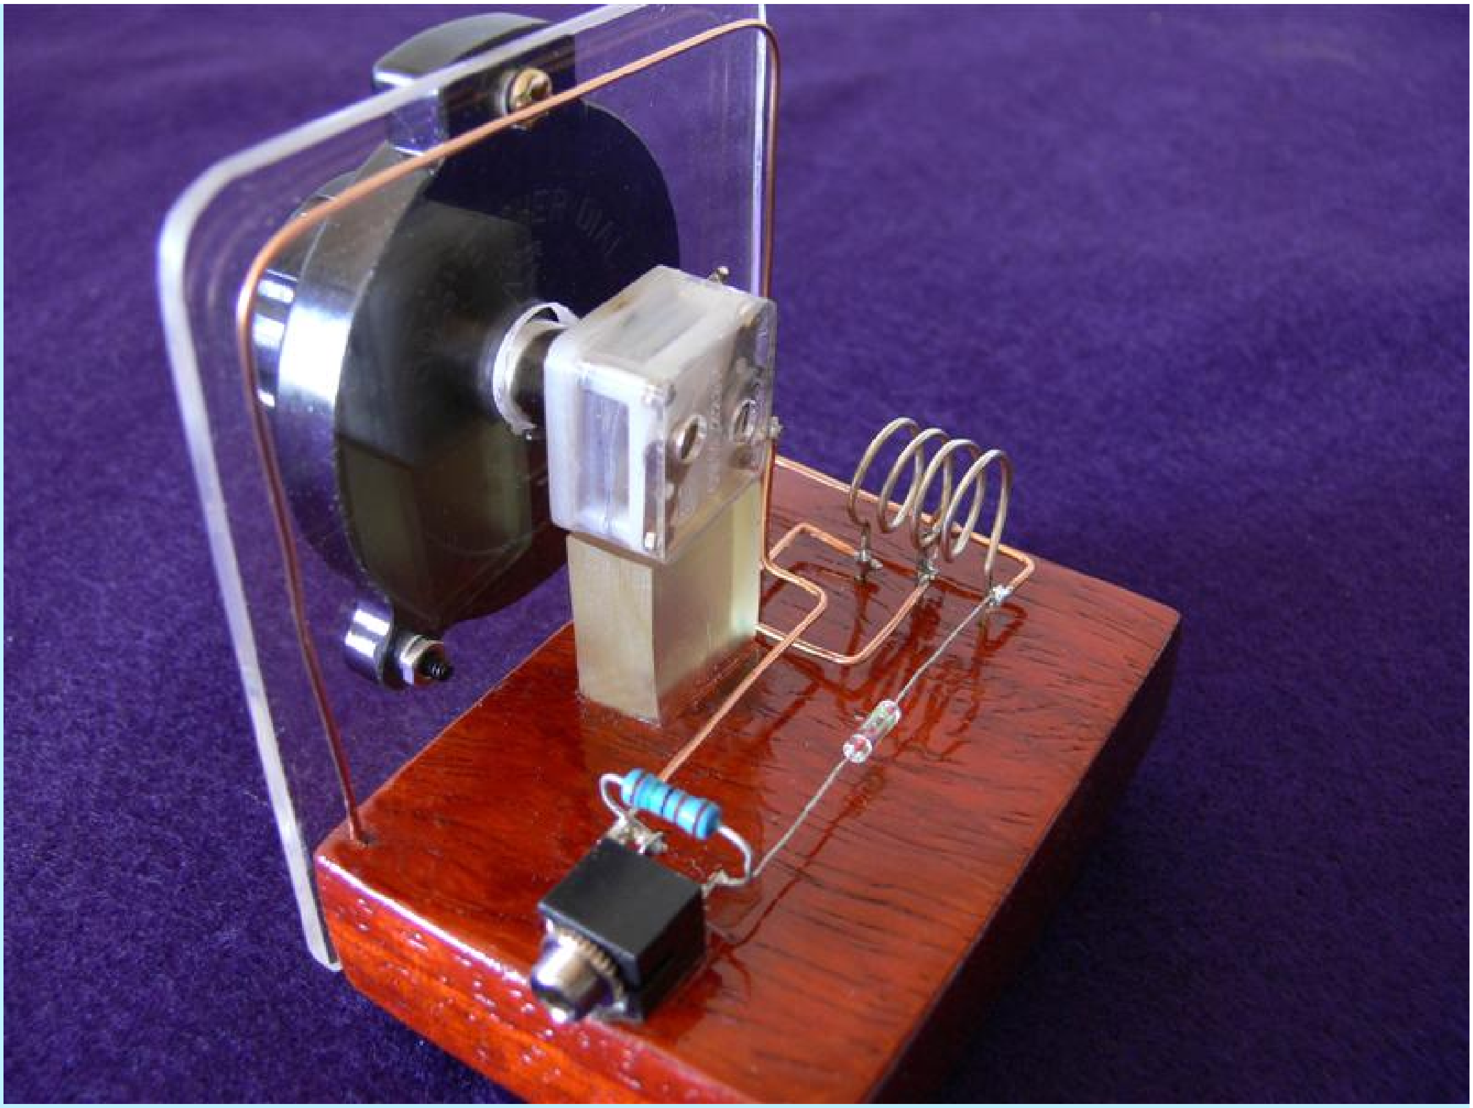
The diode is tapped directly to the antenna. The vernier dial fits directly on the tuning capacitor. The antenna parallels the perimeter of the acrylic face plate. "Military style" #18 AWG wiring is used without any insulation. It is important to keep the components physically close together. The component specifications are the same as in circuit #2. The coil is silver rather than copper, but copper does just as well. I think that the contrast of the silver and copper is beautiful. The coil was wrapped around a Sharpie Permanent Marker, then slipped off and expanded slightly. The wooden base is made from lacquered, polyurethane padouk.

I consider this set a work of art as well as science and think it is the most elegant crystal receiver I have created. I love the contrast of the silver coil, the copper antenna, the clear acrylic faceplate, the black vernier dial, the white and transparent variable capacitor, and the subtle colorings on the resistor, the diode, and the lucite base. Yet the circuit is so ridiculously simple that some will not believe it is possible without building it themselves. No shielding is necessary, and there is no problem with hand capacitance. However, the output cable position may affect reception sensitivity.

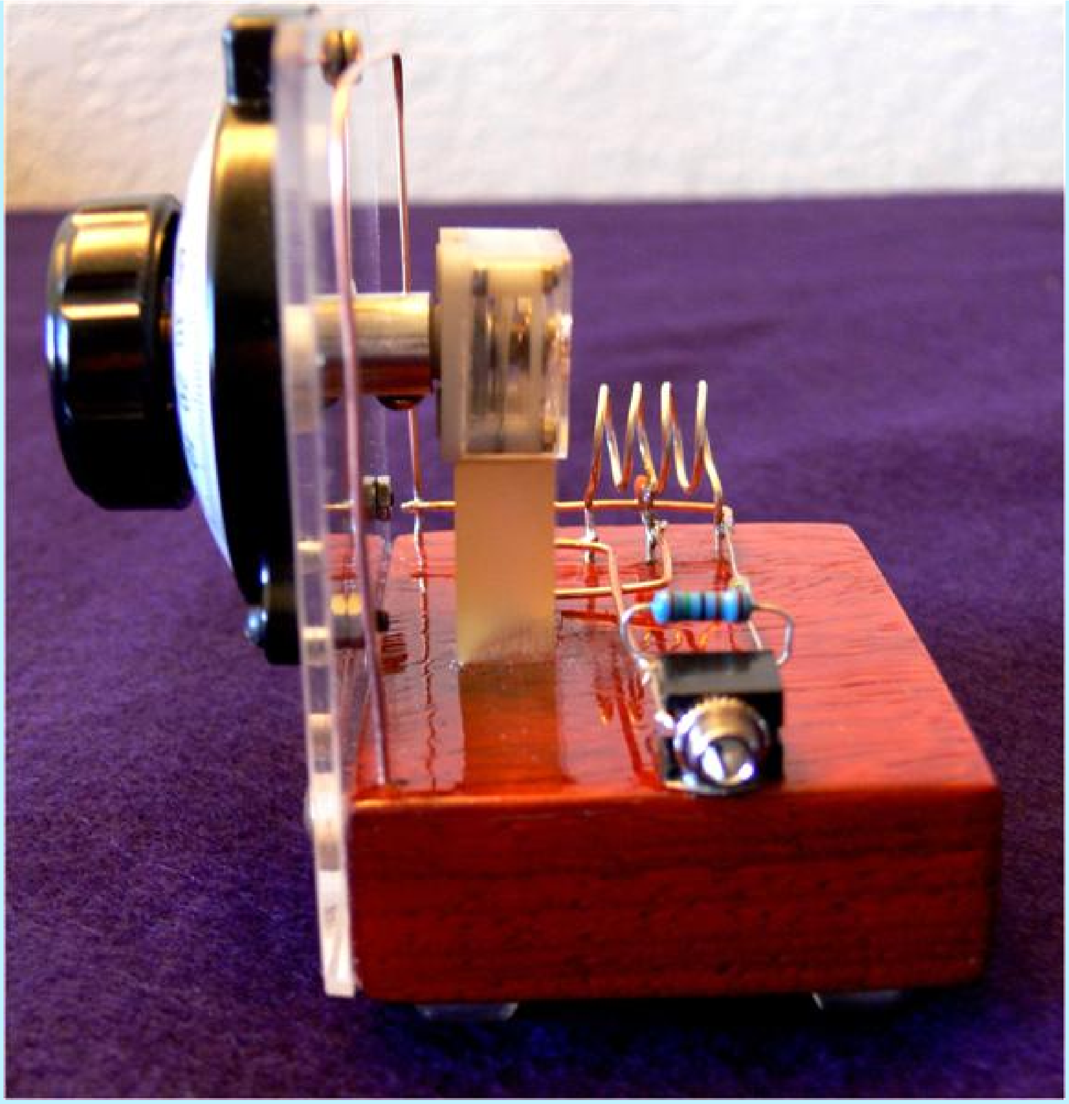
Photos of wired circuit



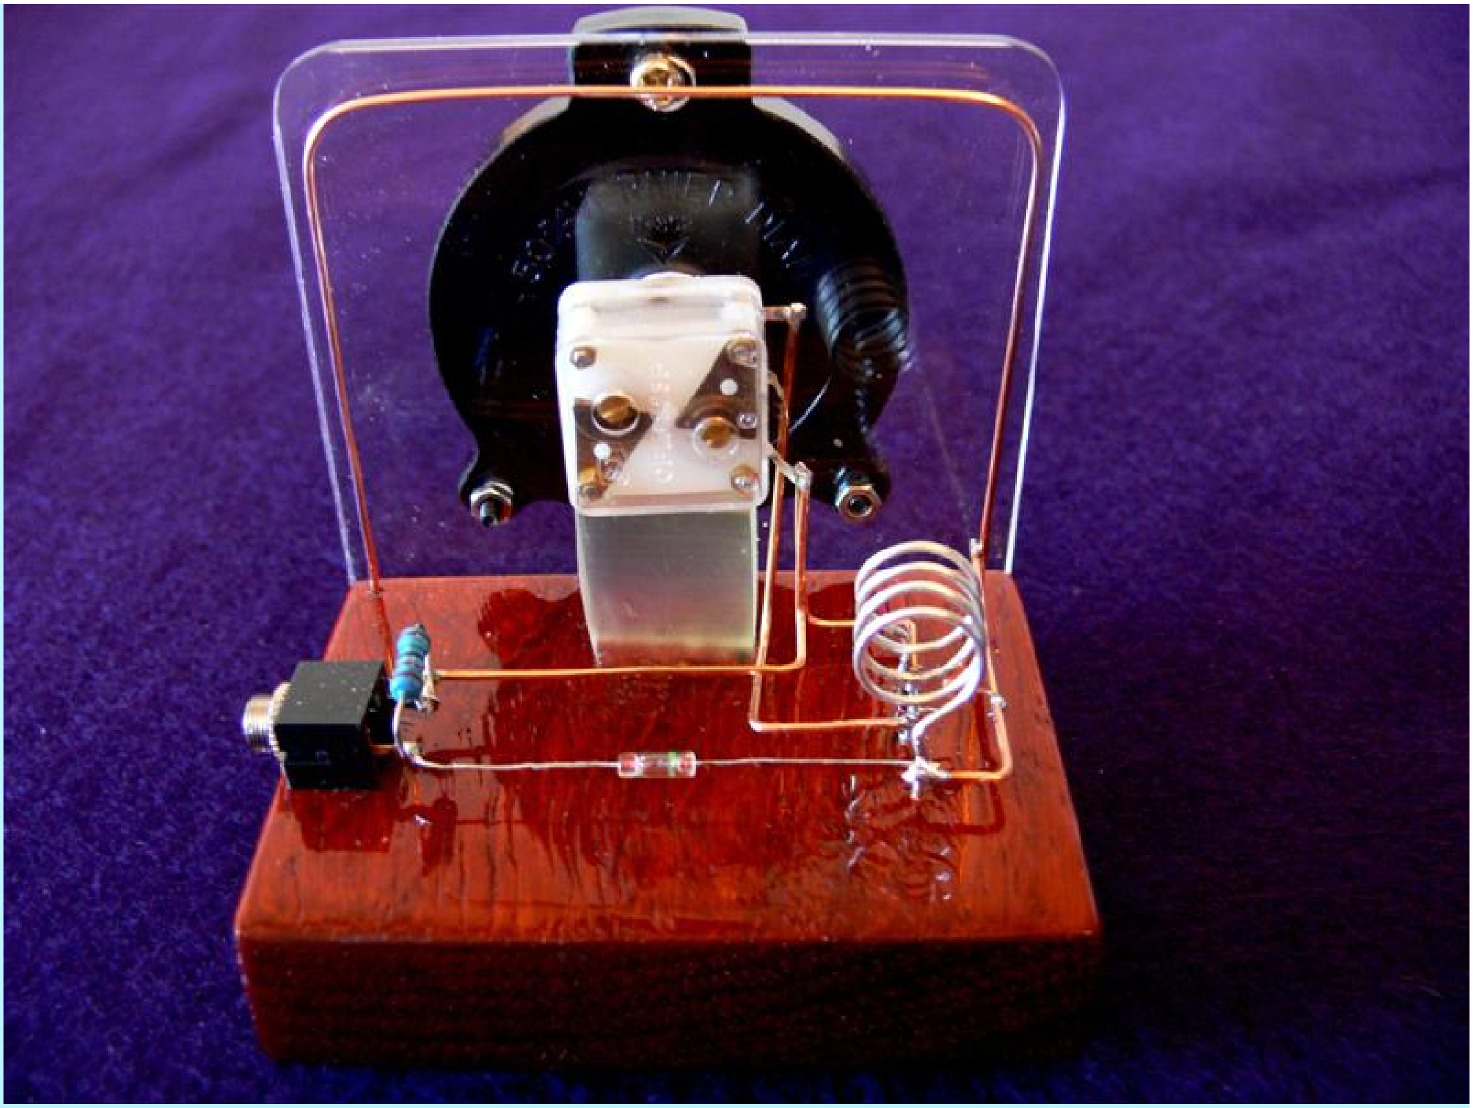
A hand is included in this photograph to show scale. Note the military style wiring, diode, and antenna. I wanted the wiring to create a modern design similar to a Mondrian painting. Not only is this set beautiful, it works! No power and no long antenna! It looks like a work of fiction.



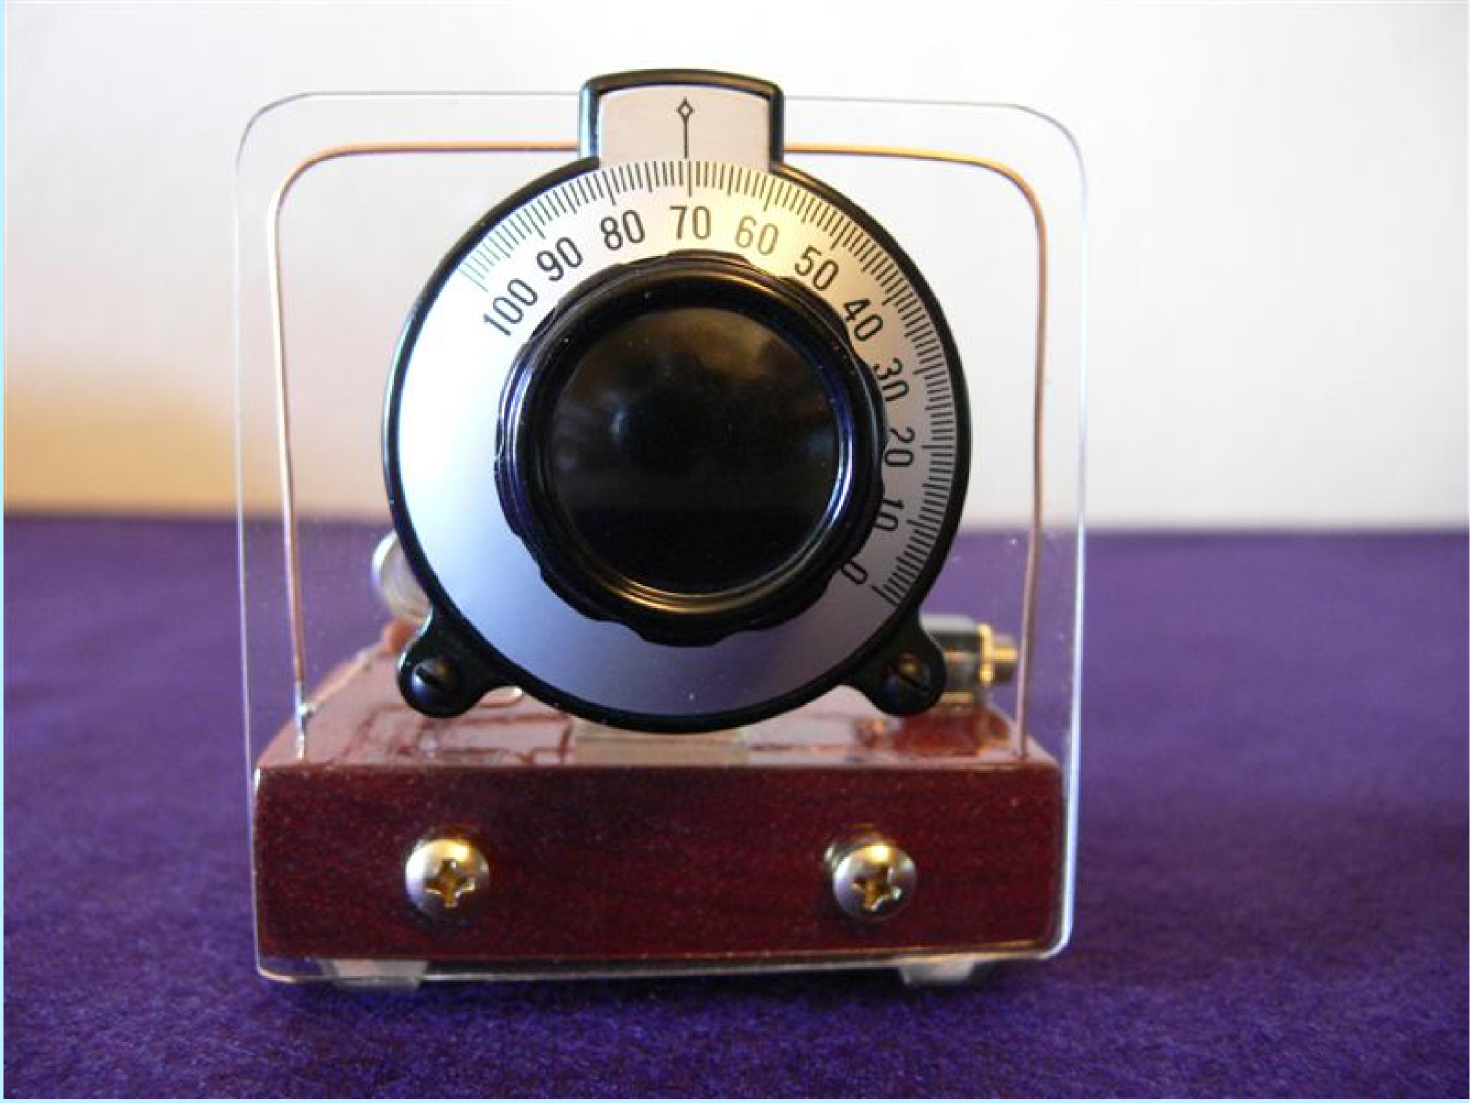
Is this thing imaginary -- science fiction? Well, imagination did play a part, but it is definitely not science fiction. This shot shows the elegance of the FM set best, I think. There is only one resistor and one fixed capacitor.



The inside of the tuning capacitor and the phono jack/output can be seen here. Can you spot the fixed ceramic capacitor? Note the polished edge of the face plate and the reflection in the wooden base.

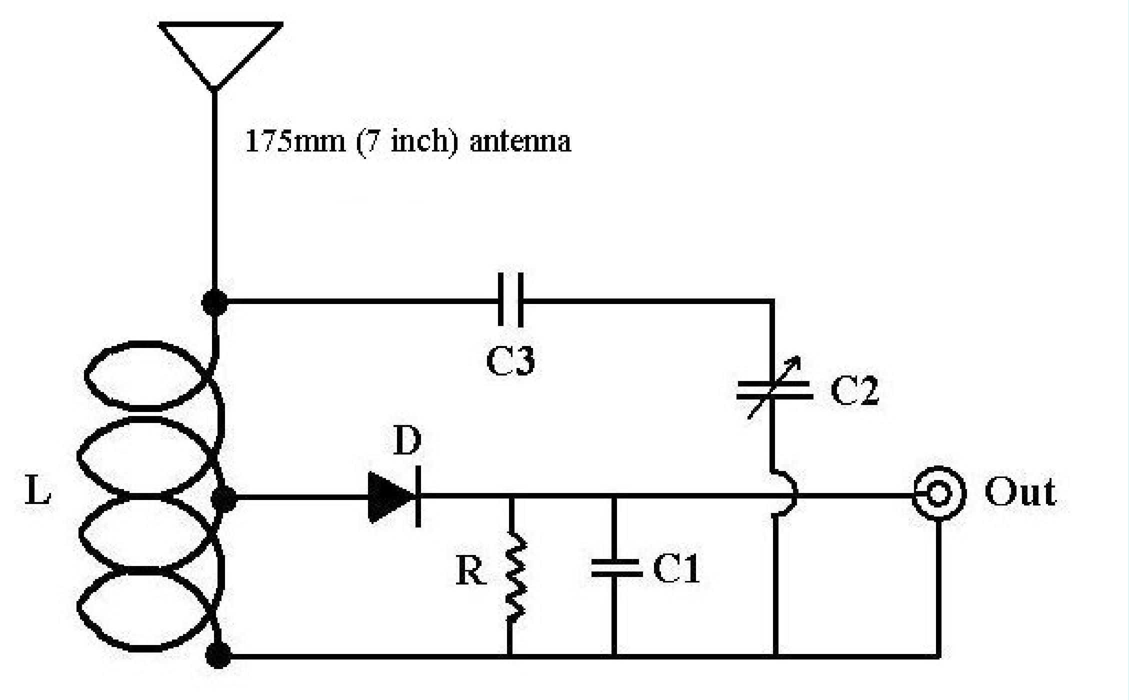


A quarter-inch piece of lucite was fitted under the tuning capacitor to anchor it. Note the two tiny trimmers on the back of the tuning capacitor. Brass screws were used to enhance appearance.



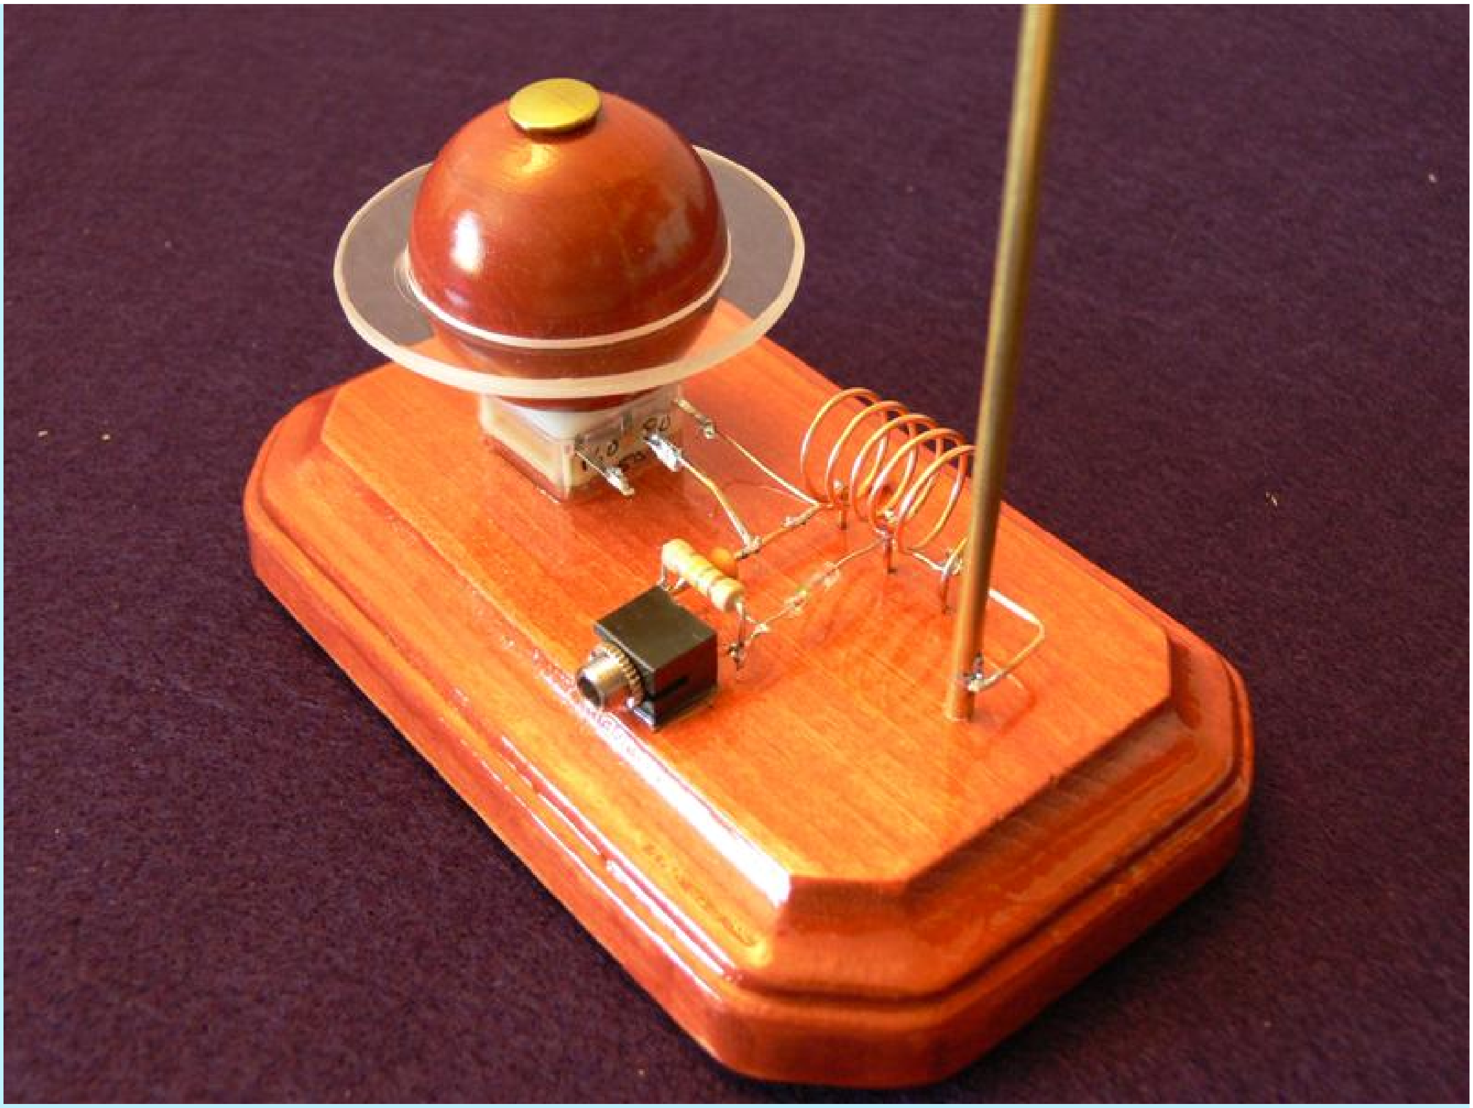
The vernier dial is large to accomodate ease of tuning, and the vernier makes it easy to separate stations. Two golden (brass) wood screws fix the face plate to the base. Holes for the face plate were made with special plastic drills, but ordinary drills may be used if drilled very SLOWLY. The knob is removable.

FM Crystal Circuit #2

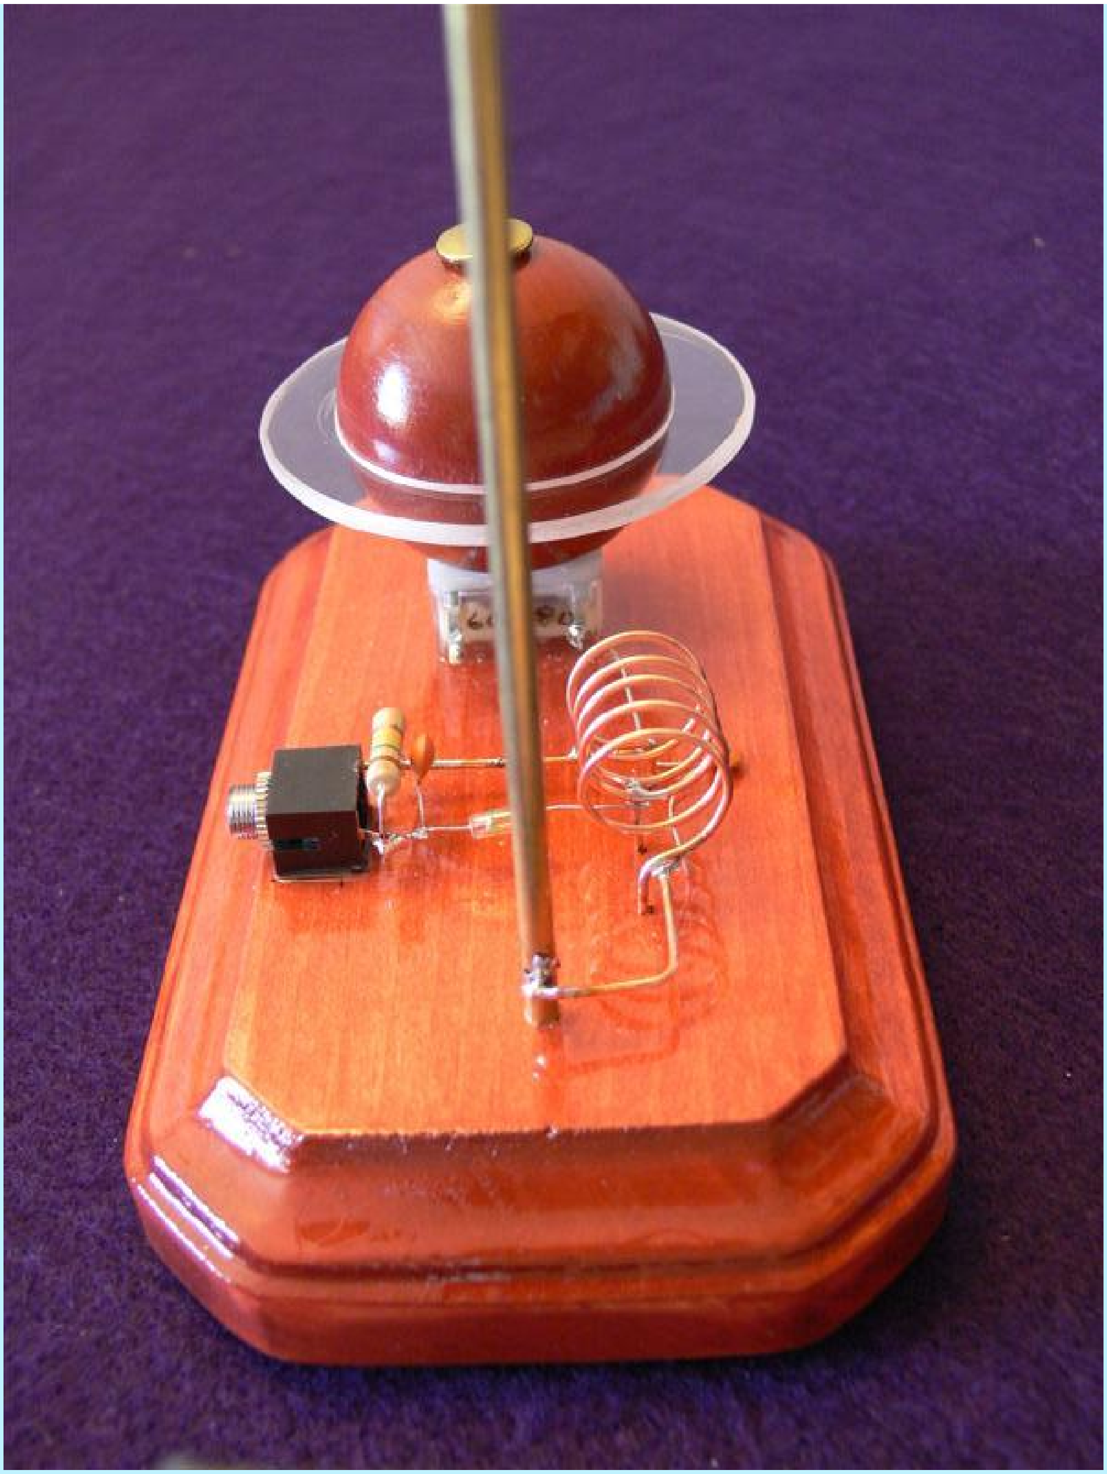


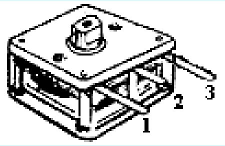
L - 5 turns AWG#18 bare copper or silver wire, 12mm inside diameter, tapped at 2.5 turns
D - 1N34 or rock crystal diode
C1 - 82 pf capacitor
C2 - 80 pf air variable capacitor
C3 - 18 pf capacitor
R - 150K resistor

The following photographs show the circuit wired with the handmade Saturn Dial. and knob. It is perhaps not as visually striking as set No. 1, but it works just as well. In fact, this set was the original version. Notice that all the wiring and coil are copper.



The Saturn dial and knob were fashioned from a "doll's head" from Michael's Arts and Crafts, a piece of lucite cut with two circle cutters, and a brass paper fastener. The knob is fixed to the tuning capacitor with a small machine screw that fits in the hole below the brass fastener. The most difficult part of this was fashioning "Saturn's rings". This must be done very carefully and slowly. The inside edge should be cut slightly undersized and then sanded with a drum sander to fit snugly. The outside edges can be sanded with fine sandpaper and polished with a plastic polisher.





The air variable capacitor may be obtained from Electronix Express at http://www.elexp.com/. Part number 14VCRF10-280P. The 80 pf side is recommended for the second circuit, contacts 2-3. Contacts 1 and 3 were used for the first circuit (50pf).

- OSC: 5-59 pf
- ANT: 5-142 pf

FM Crystal Radio

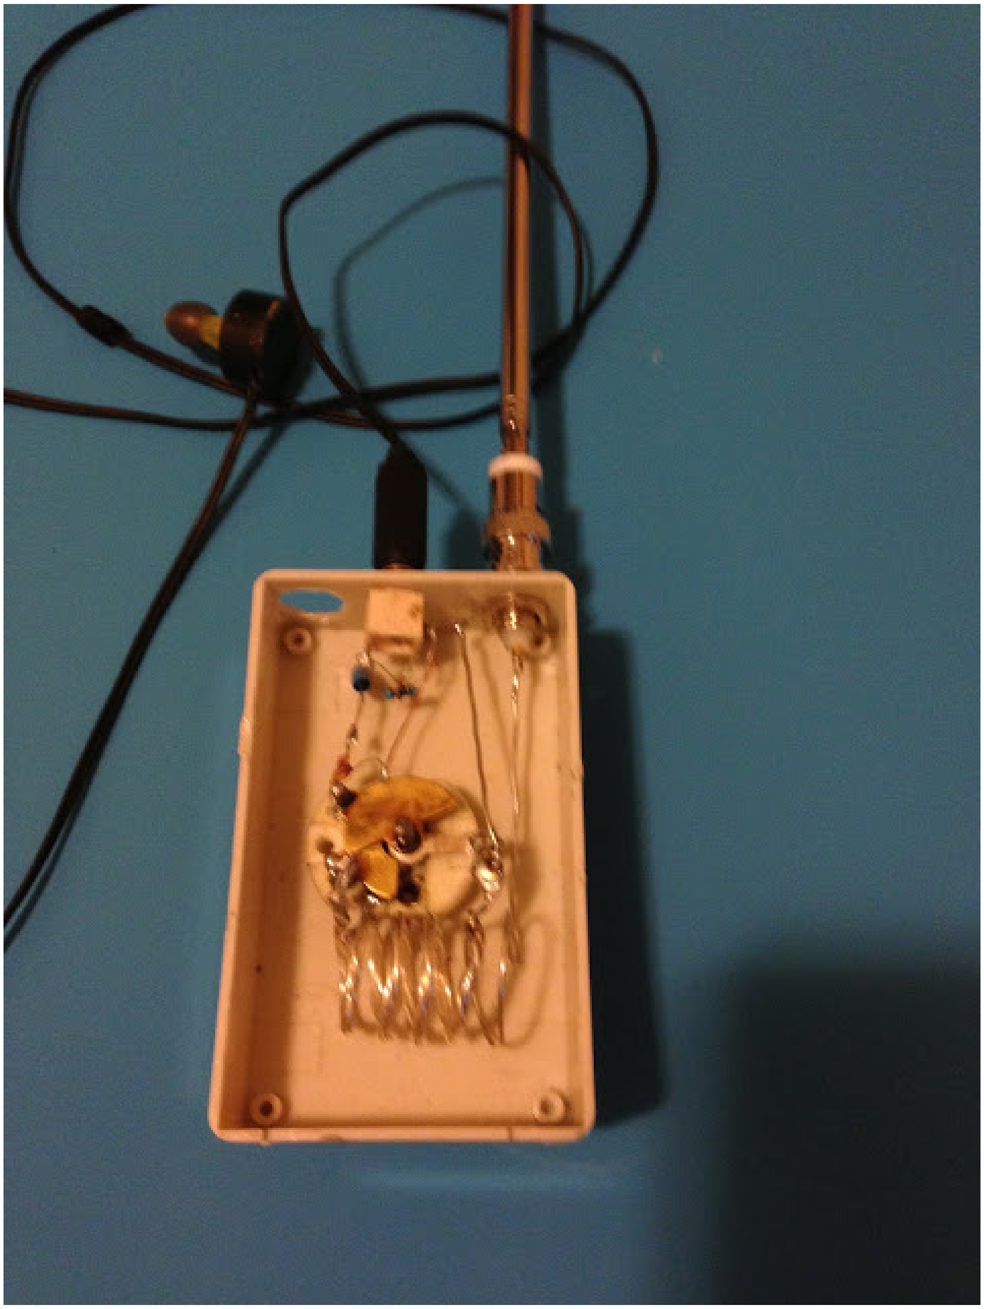
Build a battery free FM crystal radio using 1mm silver plated copper wire

[http://2.bp.blogspot.com/-LyTLmJ0D5ao/Uc2SwAO-02I/AAAAAAAABL4/jkHYmvIimcE/s1600/IMG_2535.JPG]

This FM radio runs without battery and you can listen to FM radio by just

placing this close to your window.
If reception is not good, you can attach an external FM antenna (or with antenna amplifier), instead of using the 1.2M radio antenna.

Parts you will need:
A Diode that works in high frequency (200Mhz or above, e.g. AA112, 1N34A, 1N48, Iss86 or Iss106.
A 0-12 pf AIR Variable capacitor - you can get a 0-22pf one, then remove all the copper plates and leave just 4.
50pf and 180pf fixed ceramic capacitor
100K 1/4W resistor
33uH Choke coil.
Silver platted copper wire 1mm diameter
1.2meter radio antenna.
3.5mm mini headphone jack
A high impedance 4K Ohm earphone or a crystal earphone.



[http://3.bp.blogspot.com/-NhzpbldzMyU/Uc2SwLCh3LI/AAAAAAAABL8/J7ym0UWhqqk/s1600/IMG_2536.JPG]

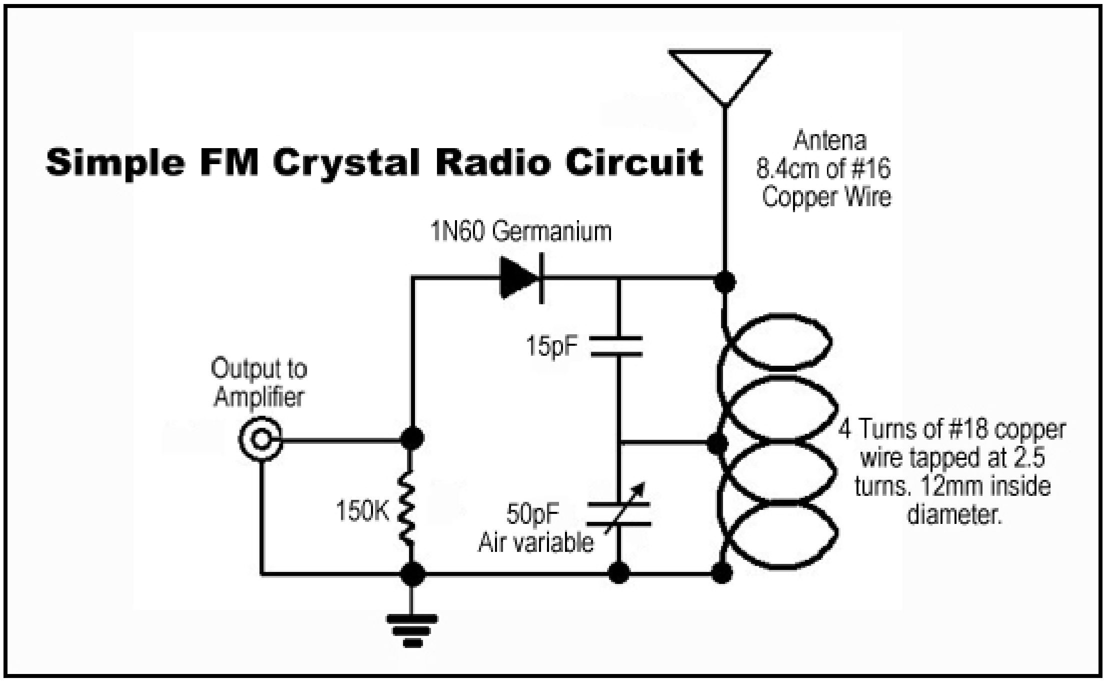
FM Crystal Radio Circuit

FM Crystal Radio Circuit



Simple FM Crystal Radio Circuit
Antena
8.4cm of #16
Copper Wire
1N60 Germanium
15pF
Output to
Amplifier
4 Turns of #18 copper
wire tapped at 2.5
turns. 12mm inside
diameter.
150K
50pF
Air variable

Parts List (some of these parts you can buy from our online store):

- 1N60 Germanium Diode
- 15pF Ceramic Capacitor
- 50pF Variable Capacitor
- 150K Ohm Resistor
- #16 & #18 Copper wires

This simple FM Crystal circuit works best near the transmitter (around 15 kilometers range). You must move the circuit around to find the best signal reception.

You can listen to FM radio stations by connecting high impedance earphones (crystal preferable) to its output or otherwise connect the circuit directly to an audio amplifier Aux input.

It is recommended to connect a "rabbit ear" antenna or hanging a short wire (15cm or so) in various positions next to the internal antenna if no signal is detected. The variable length of rabbit ears can help to tune in more stations.

Enjoy!

[57] **ABSTRACT**

A first fractal antenna of iteration N≧2 in free space exhibits characteristics including at least one resonant frequency and bandwidth. Spacing-apart the first fractal conductive element from a conductive element by a distance Δ, non-planarly or otherwise, preferably ≦0.05λ for non-planar separation for frequencies of interest decreases resonant frequency and/or introduces new resonant frequencies, widens the bandwidth, or both, for the resultant antenna system. The conductive element may itself be a fractal antenna, which if rotated relative to the first fractal antenna will alter or tune at least one characteristic of the antenna system. Forming a cut anywhere in the first fractal antenna causes new and different resonant nodes to appear. The antenna system may be tuned by cutting-off a portion of the first fractal antenna, typically increasing resonant frequency. A region of ground plane may be formed adjacent the antenna system, to form a sandwich-like system that is readily tuned. Resonator systems as well as antenna systems may be tuned using is disclosed methodology.

TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS

RELATION TO PREVIOUSLY FILED PATENT APPLICATION

This is a continuation, of application Ser. No. 08/609,514 filed Mar. 1, 1996 now abandoned, which is a continuation-in-part application of applicant's patent application Ser. No. 08/512,954 entitled FRACTAL ANTENNAS AND FRACTAL RESONATORS, filed on Aug. 9, 1995, abandoned.

FIELD OF THE INVENTION

The present invention relates to antennas and resonators, and more specifically to tuning non-Euclidian antennas and non-Euclidian resonators.

BACKGROUND OF THE INVENTION

Antenna are used to radiate and/or receive typically electromagnetic signals, preferably with antenna gain, directivity, and efficiency. Practical antenna design traditionally involves trade-offs between various parameters, including antenna gain, size, efficiency, and bandwidth.

Antenna design has historically been dominated by Euclidean geometry. In such designs, the closed antenna area is directly proportional to the antenna perimeter. For example, if one doubles the length of an Euclidean square (or "quad") antenna, the enclosed area of the antenna quadruples. Classical antenna design has dealt with planes, circles, triangles, squares, ellipses, rectangles, hemispheres, paraboloids, and the like, (as well as lines). Similarly, resonators, typically capacitors ("C") coupled in series and/or parallel with inductors ("L"), traditionally are implemented with Euclidian inductors.

With respect to antennas, prior art design philosophy has been to pick a Euclidean geometric construction, e.g., a quad, and to explore its radiation characteristics, especially with emphasis on frequency resonance and power patterns. The unfortunate result is that antenna design has far too long concentrated on the ease of antenna construction, rather than on the underlying electromagnetics.

Many prior art antennas are based upon closed-loop or island shapes. Experience has long demonstrated that small sized antennas, including loops, do not work well, one reason being that radiation resistance ("R") decreases sharply when the antenna size is shortened. A small sized loop, or even a short dipole, will exhibit a radiation pattern of ½λ and ¼λ, respectively, if the radiation resistance R is not swamped by substantially larger ohmic ("O") losses. Ohmic losses can be minimized using impedance matching networks, which can be expensive and difficult to use. But although even impedance matched small loop antennas can exhibit 50% to 85% efficiencies, their bandwidth is inherently narrow, with very high Q, e.g., Q>50. As used herein, Q is defined as (transmitted or received frequency)/(3 dB bandwidth).

As noted, it is well known experimentally that radiation resistance R drops rapidly with small area Euclidean antennas. However, the theoretical basis is not generally known, and any present understanding (or misunderstanding) appears to stem from research by J. Kraus, noted in *Antennas* (Ed. 1), McGraw Hill, New York (1950), in which a circular loop antenna with uniform current was examined. Kraus' loop exhibited a gain with a surprising limit of 1.8 dB over an isotropic radiator as loop area fells below that of a loop

having a 1λ-squared aperture. For small loops of area $A<\lambda^2/100$, radiation resistance R was given by:

$$R = K \cdot \left(\frac{A}{\lambda^2}\right)^2$$

where K is a constant, A is the enclosed area of the loop, and λ is wavelength. Unfortunately, radiation resistance R can all too readily be less than 1 Ω for a small loop antenna.

From his circular loop research Kraus generalized that calculations could be defined by antenna area rather than antenna perimeter, and that his analysis should be correct for small loops of any geometric shape. Kraus' early research and conclusions that small-sized antennas will exhibit a relatively large ohmic resistance O and a relatively small radiation resistance R, such that resultant low efficiency defeats the use of the small antenna have been widely accepted. In fact, some researchers have actually proposed reducing ohmic resistance O to 0 Ω by constructing small antennas from superconducting material, to promote efficiency.

As noted, prior art antenna and resonator design has traditionally concentrated on geometry that is Euclidean. However, one non-Euclidean geometry is fractal geometry. Fractal geometry may be grouped into random fractals, which are also termed chaotic or Brownian fractals and include a random noise components, such as depicted in FIG. **3**, or deterministic fractals such as shown in FIG. **1**C.

In deterministic fractal geometry, a self-similar structure results from the repetition of a design or motif (or "generator"), on a series of different size scales. One well known treatise in this field is *Fractals. Endlessly Repeated Geometrical Figures,* by Hans Lauwerier, Princeton University Press (1991), which treatise applicant refers to and incorporates herein by reference.

FIGS. **1**A–**2**D depict the development of some elementary forms of fractals. In FIG. **1**A, a base element **10** is shown as a straight line, although a curve could instead be used. In FIG. **1**B, a so-called Koch fractal motif or generator **20-1**, here a triangle, is inserted into base element **10**, to form a first order iteration ("N") design, e.g., N=1. In FIG. **1**C, a second order N=2 iteration design results from replicating the triangle motif **20-1** into each segment of FIG. **1**B, but where the **20-1**' version has been differently scaled, here reduced in size. As noted in the Lauwerier treatise, in its replication, the motif may be rotated, translated, scaled in dimension, or a combination of any of these characteristics. Thus, as used herein, second order of iteration or N=2 means the fundamental motif has been replicated, after rotation, translation, scaling (or a combination of each) into the first order iteration pattern. A higher order, e.g., N=3, iteration means a third fractal pattern has been generated by including yet another rotation, translation, and/or scaling of the first order motif.

In FIG. **1**D, a portion of FIG. **1**C has been subjected to a further iteration (N=3) in which scaled-down versions **20-1** of the triangle motif **20-1** have been inserted into each segment of the left half of FIG. **1**C. FIGS. **2**A–**2**C follow what has been described with respect to FIGS. **1**A–**1**C, except that a rectangular motif **20-2** has been adopted, which motif is denoted **20-2**' in FIG. **2**C, and **20-2**" in FIG. **2**D. FIG. **2**D shows a pattern in which a portion of the left-hand side is an N=3 iteration of the **20-2** rectangle motif, and in which the center portion of the figure now includes another motif, here a **20-1** type triangle motif, and in which the right-hand side of the figure remains an N=2 iteration.

Traditionally, non-Euclidean designs including random fractals have been understood to exhibit antiresonance characteristics with mechanical vibrations. It is known in the art to attempt to use non-Euclidean random designs at lower frequency regimes to absorb, or at least not reflect sound due to the antiresonance characteristics. For example, M. Schroeder in *Fractals, Chaos, Power Laws* (1992), W. H. Freeman, New York discloses the use of presumably random or chaotic fractals in designing sound blocking diffusers for recording studios and auditoriums.

Experimentation with non-Euclidean structures has also been undertaken with respect to electromagnetic waves, including radio antennas. In one experiment, Y. Kim and D. Jaggard in *The Fractal Random Array,* Proc. IEEE 74, 1278–1280 (1986) spread-out antenna elements in a sparse microwave array, to minimize sidelobe energy without having to use an excessive number of elements. But Kim and Jaggard did not apply a fractal condition to the antenna elements, and test results were not necessarily better than any other techniques, including a totally random spreading of antenna elements. More significantly, the resultant array was not smaller than a conventional Euclidean design.

Prior art spiral antennas, cone antennas, and V-shaped antennas may be considered as a continuous, deterministic first order fractal, whose motif continuously expands as distance increases from a central point. A log-periodic antenna may be considered a type of continuous fractal in that it is fabricated from a radially expanding structure. However, log periodic antennas do not utilize the antenna perimeter for radiation, but instead rely upon an arc-like opening angle in the antenna geometry. Such opening angle is an angle that defines the size-scale of the log-periodic structure, which structure is proportional to the distance from the antenna center multiplied by the opening angle. Further, known log-periodic antennas are not necessarily smaller than conventional driven element-parasitic element antenna designs of similar gain.

Unintentionally, first order fractals have been used to distort the shape of dipole and vertical antennas to increase gain, the shapes being defined as a Brownian-type of chaotic fractals. See F. Landstorfer and R. Sacher, *Optimisation of Wire Antennas,* J. Wiley, New York (1985). FIG. **3** depicts three bent-vertical antennas developed by Landstorfer and Sacher through trial and error, the plots showing the actual vertical antennas as a function of x-axis and y-axis coordinates that are a function of wavelength. The "EF" and "BF" nomenclature in FIG. **3** refer respectively to end-fire and back-fire radiation patterns of the resultant bent-vertical antennas.

First order fractals have also been used to reduce horn-type antenna geometry, in which a double-ridge horn configuration is used to decrease resonant frequency. See J. Kraus in *Antennas,* McGraw Hill, New York (1885). The use of rectangular, box-like, and triangular shapes as impedance-matching loading elements to shorten antenna element dimensions is also known in the art.

Whether intentional or not, such prior art attempts to use a quasi-fractal or fractal motif in an antenna employ at best a first order iteration fractal. By first iteration it is meant that one Euclidian structure is loaded with another Euclidean structure in a repetitive fashion, using the same size for repetition. FIG. **1**C, for example, is not first order because the **20-1**' triangles have been shrunk with respect to the size of the first motif **20-1**.

Prior art antenna design does not attempt to exploit multiple scale self-similarity of real fractals. This is hardly surprising in view of the accepted conventional wisdom that because such antennas would be anti-resonators, and/or if suitably shrunken would exhibit so small a radiation resistance R, that the substantially higher ohmic losses O would result in too low an antenna efficiency for any practical use. Further, it is probably not possible to mathematically predict such an antenna design, and high order iteration fractal antennas would be increasingly difficult to fabricate and erect, in practice.

FIGS. **4**A and **4**B depict respective prior art series and parallel type resonator configurations, comprising capacitors C and Euclidean inductors L. In the series configuration of FIG. **4**A, a notch-filter characteristic is presented in that the impedance from port A to port B is high except at frequencies approaching resonance, determined by $1/\sqrt{(LC)}$.

In the distributed parallel configuration of FIG. **4**B, a low-pass filter characteristic is created in that at frequencies below resonance, there is a relatively low impedance path from port A to port B, but at frequencies greater than resonant frequency, signals at port A are shunted to ground (e.g., common terminals of capacitors C), and a high impedance path is presented between port A and port B. Of course, a single parallel LC configuration may also be created by removing (e.g., short-circuiting) the rightmost inductor L and right two capacitors C, in which case port B would be located at the bottom end of the leftmost capacitor C.

In FIGS. **4**A and **4**B, inductors L are Euclidean in that increasing the effective area captured by the inductors increases with increasing geometry of the inductors, e.g., more or larger inductive windings or, if not cylindrical, traces comprising inductance. In such prior art configurations as FIGS. **4**A and **4**B, the presence of Euclidean inductors L ensures a predictable relationship between L, C and frequencies of resonance.

Applicant's above-noted FRACTAL ANTENNA AND FRACTAL RESONATORS patent application provides a design methodology that can produce smaller-scale antennas that exhibit at least as much gain, directivity, and efficiency as larger Euclidean counterparts. Such design approach should exploit the multiple scale self-similarity of real fractals, including $N>2$ iteration order fractals. Further, as respects resonators, said application discloses a non-Euclidean resonator whose presence in a resonating configuration can create frequencies of resonance beyond those normally presented in series and/or parallel LC configurations.

However, there is a need for a simple mechanism to tune and/or otherwise adjust such antennas and resonators.

The present invention provides such mechanisms.

SUMMARY OF THE INVENTION

The present invention tunes fractal antenna systems and resonator systems, preferably designed according to applicant's above-reference patent application, by placing an active (or driven) fractal antenna or resonator a distance Δ from a second conductor. Such disposition of the antenna and second conductor advantageously lowers resonant frequencies and widens bandwidth for the fractal antenna. In some embodiments, the fractal antenna and second conductor are non-coplanar and λ is the separation distance therebetween, preferably $\leqq 0.05\lambda$ for the frequency of interest $(1/\lambda)$. In other embodiments, the fractal antenna and second conductive element may be planar, in which case λ a separation distance, measured on the common plane.

The second conductor may in fact be a second fractal antenna of like or unlike configuration as the active antenna. Varying the distance Δ tunes the active antenna and thus the overall system. Further, if the second element, preferably a fractal antenna, is angularly rotated relative to the active antenna, resonant frequencies of the active antenna may be varied.

Providing a cut in the fractal antenna results in new and different resonant nodes, including resonant nodes having perimeter compression parameters, defined below, ranging from about three to ten. If desired, a portion of a fractal antenna may be cutaway and removed so as to tune the antenna by increasing resonance(s).

Tunable fractal antenna systems need not be planar, according to the present invention. Fabricating a fractal antenna around a form such as a torroid ring, or forming the fractal antenna on a flexible substrate that is curved about itself results in field self-proximity that produces resonant frequency shifts. A fractal antenna and a conductive element may each be formed as a curved surface or even as a torroid-shape, and placed in sufficiently close proximity to each other to provide a useful tuning and system characteristic altering mechanism.

In the various embodiments, more than two elements may be used, and tuning may be accomplished by varying one or more of the parameters associated with one or more elements.

Preferably fractal antennas and resonators so tuned are designed according to applicant's above-referenced patent application, which provides an antenna having at least one element whose shape, at least is part, is substantially a deterministic fractal of iteration order $N \geqq 2$. Using fractal geometry, the antenna element has a self-similar structure resulting from the repetition of a design or motif (or "generator") that is replicated using rotation, and/or translation, and/or scaling. The fractal element will have x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, yb_N)$ and $y_{N+1}=g(x_N, y_N$, where x_N, y_N define coordinates for a preceding iteration, and where f(x,y) and g(x,y) are functions defining the fractal motif and behavior.

In contrast to Euclidean geometric antenna design, applicant's deterministic fractal antenna elements have a perimeter that is not directly proportional to area. For a given perimeter dimension, the enclosed area of a multi-iteration fractal will always be as small or smaller than the area of a corresponding conventional Euclidean antenna.

A fractal antenna has a fractal ratio limit dimension D given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization, respectively.

As used with the present invention, a fractal antenna perimeter compression parameter (PC) is defined as:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC=A\cdot\log\,[N(D+C)]$$

in which A and C are constant coefficients for a given fractal motif, N is an iteration number, and D is the fractal dimension, defined above.

Radiation resistance (R) of a fractal antenna decreases as a small power of the perimeter compression (PC), with a fractal loop or island always exhibiting a substantially higher radiation resistance than a small Euclidean loop antenna of equal size. In the present invention, deterministic fractals are used wherein A and C have large values, and thus provide the greatest and most rapid element-size shrinkage. A fractal antenna according to the present invention will exhibit an increased effective wavelength.

The number of resonant nodes of a fractal loop-shaped antenna according to the present invention increases as the iteration number N and is at least as large as the number of resonant nodes of an Euclidean island with the same area. Further, resonant frequencies of a fractal antenna include frequencies that are not harmonically related.

A fractal antenna according to the present invention is smaller than its Euclidean counterpart but provides at least as much gain and frequencies of resonance and provides essentially a 50 Ω termination impedance at its lowest resonant frequency. Further, the fractal antenna exhibits non-harmonically frequencies of resonance, a low Q and resultant good bandwidth, acceptable standing wave ratio ("SWR"), a radiation impedance that is frequency dependent, and high efficiencies. Fractal inductors of first or higher iteration order may also be provided in LC resonators, to provide additional resonant frequencies including non-harmonically related frequencies.

Other features and advantages of the invention will appear from the following description in which the preferred embodiments have been set forth in detail, in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1**A depicts a base element for an antenna or an inductor, according to the prior art;

FIG. **1**B depicts a triangular-shaped Koch fractal motif, according to the prior art;

FIG. **1**C depicts a second-iteration fractal using the motif of FIG. **1**B, according to the prior art;

FIG. **1**D depicts a third-iteration fractal using the motif of FIG. **1**B, according to the prior art;

FIG. **2**A depicts a base element for an antenna or an inductor, according to the prior art;

FIG. **2**B depicts a rectangular-shaped Minkowski fractal motif, according to the prior art;

FIG. **2**C depicts a second-iteration fractal using the motif of FIG. **2**B, according to the prior art;

FIG. **2**D depicts a fractal configuration including a third-order using the motif of FIG. **2**B, as well as the motif of FIG. **1**B, according to the prior art;

FIG. **3** depicts bent-vertical chaotic fractal antennas, according to the prior art;

FIG. **4**A depicts a series L-C resonator, according to the prior art;

FIG. **4**B depicts a distributed parallel L-C resonator, according to the prior art;

FIG. **5**A depicts an Euclidean quad antenna system, according to the prior art;

FIG. **5**B depicts a second-order Minkowski island fractal quad antenna, according to the present invention;

FIG. **6** depicts an ELNEC-generated free-space radiation pattern for an MI-2 fractal antenna, according to the present invention;

FIG. **7**A depicts a Cantor-comb fractal dipole antenna, according to the present invention;

FIG. **7**B depicts a torn square fractal quad antenna, according to the present invention;

FIG. **7**C-**1** depicts a second iteration Minkowski (MI-2) printed circuit fractal antenna, according to the present invention;

FIG. **7**C-**2** depicts a second iteration Minkowski (MI-2) slot fractal antenna, according to the present invention;

FIG. **7**D depicts a deterministic dendrite fractal vertical antenna, according to the present invention;

FIG. **7**E depicts a third iteration Minkowski island (MI-3) fractal quad antenna, according to the present invention;

FIG. **7**F depicts a second iteration Koch fractal dipole, according to the present invention;

FIG. **7**G depicts a third iteration dipole, according to the present invention;

FIG. **7**H depicts a second iteration Minkowski fractal dipole, according to the present invention;

FIG. **7**I depicts a third iteration multi-fractal dipole, according to the present invention;

FIG. **8**A depicts a generic system in which a passive or active electronic system communicates using a fractal antenna, according to the present invention;

FIG. **8**B depicts a communication system in which several fractal antennas are electronically selected for best performance, according to the present invention;

FIG. **8**C depicts a communication system in which electronically steerable arrays of fractal antennas are electronically selected for best performance, according to the present invention;

FIG. **9**A depicts fractal antenna gain as a function of iteration order N, according to the present invention;

FIG. **9**B depicts perimeter compression PC as a function of iteration order N for fractal antennas, according to the present invention;

FIG. **10**A depicts a fractal inductor for use in a fractal resonator, according to the present invention;

FIG. **10**B depicts a credit card sized security device utilizing a fractal resonator, according to the present invention;

FIG. **11**A depicts an embodiment in which a fractal antenna is spaced-apart a distance Δ from a conductor element to vary resonant properties and radiation characteristics of the antenna, according to the present invention;

FIG. **11**B depicts an embodiment in which a fractal antenna is coplanar with a ground plane and is spaced-apart a distance Δ' from a coplanar passive parasitic element to vary resonant properties and radiation characteristics of the antenna, according to the present invention;

FIG. **12**A depicts spacing-apart first and second fractal antennas a distance Δ to decrease resonance and create additional resonant frequencies for the active or driven antenna, according to the present invention;

FIG. **12**B depicts relative angular rotation between spaced-apart first and second fractal antennas Δ to vary resonant frequencies of the active or driven antenna, according to the present invention;

FIG. **13**A depicts cutting a fractal antenna or resonator to create different resonant nodes and to alter perimeter compression, according to the present invention;

FIG. **13**B depicts forming a non-planar fractal antenna or resonator on a flexible substrate that is curved to shift resonant frequency, apparently due to self-proximity electromagnetic fields, according to the present invention;

FIG. **13**C depicts forming a fractal antenna or resonator on a curved torroidal form to shift resonant frequency, apparently due to self-proximity electromagnetic fields, according to the present invention;

FIG. **14**A depicts forming a fractal antenna or resonator in which the conductive element is not attached to the system coaxial or other feedline, according to the present invention;

FIG. **14**B depicts a system similar to FIG. **14**A, but demonstrates that the driven fractal antenna may be coupled to the system coaxial or other feedline at any point along the antenna, according to the present invention;

FIG. **14**C depicts an embodiment in which a supplemental ground plane is disposed adjacent a portion of the driven fractal antenna and conductive element, forming a sandwich-like system, according to the present invention;

FIG. **14**D depicts an embodiment in which a fractal antenna system is tuned by cutting away a portion of the driven antenna, according to the present invention;

FIG. **15** depicts a communication system similar to that of FIG. **8**A, in which several fractal antennas are tunable and are electronically selected for best performance, according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

In overview, the present invention provides an antenna having at least one element whose shape, at least is part, is substantially a fractal of iteration order $N \geqq 2$. The resultant antenna is smaller than its Euclidean counterpart, provides a 50 Ω termination impedance, exhibits at least as much gain and more frequencies of resonance than its Euclidean counterpart, including non-harmonically related frequencies of resonance, exhibits a low Q and resultant good bandwidth, acceptable SWR, a radiation impedance that is frequency dependent, and high efficiencies.

In contrast to Euclidean geometric antenna design, fractal antenna elements according to the present invention have a perimeter that is not directly proportional to area. For a given perimeter dimension, the enclosed area of a multi-iteration fractal area will always be at least as small as any Euclidean area.

Using fractal geometry, the antenna element has a self-similar structure resulting from the repetition of a design or motif (or "generator"), which motif is replicated using rotation, translation, and/or scaling (or any combination thereof). The fractal portion of the element has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, yb_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates of a preceding iteration, and where f(x,y) and g(x,y) are functions defining the fractal motif and behavior.

For example, fractals of the Julia set may be represented by the form:

$$x_{N+1}=x_N^2-y_N^2+a$$

$$y_{N+1}=2x_N \cdot y_N=b$$

In complex notation, the above may be represented as:

$$z_{N+1}=z_N^2+c$$

Although it is apparent that fractals can comprise a wide variety of forms for functions f(x,y) and g(x,y), it is the iterative nature and the direct relation between structure or morphology on different size scales that uniquely distinguish f(x,y) and g(x,y) from non-fractal forms. Many references including the Lauwerier treatise set forth equations appropriate for f(x,y) and g(x,y).

Iteration (N) is defined as the application of a fractal motif over one size scale. Thus, the repetition of a single size scale of a motif is not a fractal as that term is used herein. Multi-fractals may of course be implemented, in which a motif is changed for different iterations, but eventually at least one motif is repeated in another iteration.

An overall appreciation of the present invention may be obtained by comparing FIGS. **5A** and **5B**. FIG. **5A** shows a conventional Euclidean quad antenna **5** having a driven element **10** whose four sides are each 0.25λlong, for a total perimeter of 1λ, where λ is the frequency of interest.

Euclidean element **10** has an impedance of perhaps 130 Ω, which impedance decreases if a parasitic quad element **20** is spaced apart on a boom **30** by a distance B of 0.1λ to 0.25λ. Parasitic element **20** is also sized S=0.25λ on a side, and its presence can improve directivity of the resultant two-element quad antenna. Element **10** is depicted in FIG. **5A** with heavier lines than element **20**, solely to avoid confusion in understanding the figure. Non-conductive spreaders **40** are used to help hold element **10** together and element **20** together.

Because of the relatively large drive impedance, driven element **10** is coupled to an impedance matching network or device **60**, whose output impedance is approximately 50 Ω. A typically 50 Ω coaxial cable **50** couples device **60** to a transceiver **70** or other active or passive electronic equipment **70**.

As used herein, the term transceiver shall mean a piece of electronic equipment that can transmit, receive, or transmit and receive an electromagnetic signal via an antenna, such as the quad antenna shown in FIG. **5A** or **5B**. As such, the term transceiver includes without limitation a transmitter, a receiver, a transmitter-receiver, a cellular telephone, a wireless telephone, a pager, a wireless computer local area network ("LAN") communicator, a passive resonant unit used by stores as part of an anti-theft system in which transceiver **70** contains a resonant circuit that is blown or not-blown by an electronic signal at time of purchase of the item to which transceiver **70** is affixed, resonant sensors and transponders, and the like.

Further, since antennas according to the present invention can receive incoming radiation and coupled the same as alternating current into a cable, it will be appreciated that fractal antennas may be used to intercept incoming light radiation and to provide a corresponding alternating current. For example, a photocell antenna defining a fractal, or indeed a plurality or array of fractals, would be expected to output more current in response to incoming light than would a photocell of the same overall array size. FIG. **5B** depicts a fractal quad antenna **95**, designed to resonant at the same frequency as the larger prior art antenna **5** shown in FIG. **5A**. Driven element **100** is seen to be a second order fractal, here a so-called Minkowski island fractal, although any of numerous other fractal configurations could instead be used, including without limitation, Koch, torn square, Mandelbrot, Caley tree, monkey's swing, Sierpinski gasket, and Cantor gasket geometry.

If one were to measure the amount of conductive wire or conductive trace comprising the perimeter of element **10** or element **20**, it would be perhaps 40% greater than the 1.0λ for the Euclidean quad of FIG. **5A**. However, for fractal antenna **95**, the physical straight length of one element side KS will be substantially smaller, and for the N=2 fractal antenna shown in FIG. **5B**, KS≈0.13λ (in air), compared with K≈0.25λ for prior art antenna **5**.

However, although the actual perimeter length of element **100** is greater than the 1λ perimeter of prior art element **10**, the area within antenna element **100** is substantially less than the S^2 area of prior art element **10**. As noted, this area independence from perimeter is a characteristic of a deterministic fractal. Boom length B for antenna **95** will be slightly different from length B for prior art antenna **5** shown in FIG. **5A**. In FIG. **5B**, a parasitic element **120**, which preferably is similar to driven element **100** but need not be, may be attached to boom **130**. For ease of illustration FIG. **5B** does not depict non-conductive spreaders, such as spreaders **40** shown in FIG. **5A**, which help hold element **100** together and element **120** together. Further, for ease of understanding the figure, element **10** is drawn with heavier lines than element **120**, to avoid confusion in the portion of the figure in which elements **100** and **120** appear overlapped.

An impedance matching device **60** is advantageously unnecessary for the fractal antenna of FIG. **5B**, as the driving impedance of element **100** is about 50 Ω, e.g., a perfect match for cable **50** if reflector element **120** is absent, and about 35Ω, still an acceptable impedance match for cable **50**, if element **120** is present. Antenna **95** may be fed by cable **50** essentially anywhere in element **100**, e.g., including locations X, Y, Z, among others, with no substantial change in the termination impedance. With cable **50** connected as shown, antenna **95** will exhibit horizontal polarization. If vertical polarization is desired, connection may be made as shown by cable **50'**. If desired, cables **50** and **50'** may both be present, and an electronic switching device **75** at the antenna end of these cables can short-out one of the cables. If cable **50** is shorted out at the antenna, vertical polarization results, and if instead cable **50'** is shorted out at the antenna, horizontal polarization results.

As shown by Table **3** herein, fractal quad **95** exhibits about 1.5 dB gain relative to Euclidean quad 10. Thus, transmitting power output by transceiver **70** may be cut by perhaps 40% and yet the system of FIG. **5B** will still perform no worse than the prior art system of FIG. **5A**. Further, as shown by Table 1, the fractal antenna of FIG. **5B** exhibits more resonance frequencies than the antenna of FIG. **5B**, and also exhibits some resonant frequencies that are not harmonically related to each other. As shown by Table 3, antenna **95** has efficiency exceeding about 92% and exhibits an excellent SWR of about 1.2:1. As shown by Table 5, applicant's fractal quad antenna exhibits a relatively low value of Q. This result is surprising in view of conventional prior art wisdom to the effect that small loop antennas will exhibit high Q.

In short, that fractal quad **95** works at all is surprising in view of the prior art (mis)understanding as to the nature of radiation resistance R and ohmic losses O. Indeed, the prior art would predict that because the fractal antenna of FIG. **5B** is smaller than the conventional antenna of FIG. **5A**, efficiency would suffer due to an anticipated decrease in radiation resistance R. Further, it would have been expected that Q would be unduly high for a fractal quad antenna.

FIG. **6** is an ELNEC-generated free-space radiation pattern for a second-iteration Minkowski fractal antenna, an antenna similar to what is shown in FIG. **5B** with the parasitic element **120** omitted. The frequency of interest was 42.3 MHz, and a 1.5:1 SWR was used. In FIG. **6**, the outer ring represents 2.091 dBi, and a maximum gain of 2.091 dBi. (ELNEC is a graphics/PC version of MININEC, which is a PC version of NEC.) In practice, however, the data shown in FIG. **6** were conservative in that a gain of 4.8 dB above an isotropic reference radiator was actually obtained. The error in the gain figures associated with FIG. **6** presumably is due to roundoff and other limitations inherent in the ELNEC program. Nonetheless, FIG. **6** is believed to accurately depict the relative gain radiation pattern of a single element Minkowski (MI-2) fractal quad according to the present invention.

FIG. **7A** depicts a third iteration Cantor-comb fractal dipole antenna, according to the present invention. Generation of a Cantor-comb involves trisecting a basic shape, e.g., a rectangle, and providing a rectangle of one-third of the basic shape on the ends of the basic shape. The new smaller rectangles are then trisected, and the process repeated. FIG. **7B** is modelled after the Lauwerier treatise, and depicts a single element torn-sheet fractal quad antenna.

FIG. **7C-1** depicts a printed circuit antenna, in which the antenna is fabricated using printed circuit or semiconductor fabrication techniques. For ease of understanding, the etched-away non-conductive portion of the printed circuit board **150** is shown cross-hatched, and the copper or other conductive traces **170** are shown without cross-hatching.

Applicant notes that while various corners of the Minkowski rectangle motif may appear to be touching in this and perhaps other figures herein, in fact no touching occurs. Further, it is understood that it suffices if an element according to the present invention is substantially a fractal. By this it is meant that a deviation of less than perhaps 10% from a perfectly drawn and implemented fractal will still provide adequate fractal-like performance, based upon actual measurements conducted by applicant.

The substrate **150** is covered by a conductive layer of material **170** that is etched away or otherwise removed in areas other than the fractal design, to expose the substrate **150**. The remaining conductive trace portion **170** defines a fractal antenna, a second iteration Minkowski slot antenna in FIG. **7C**. Substrate **150** may be a silicon wafer, a rigid or a flexible plastic-like material, perhaps Mylar™ material, or the non-conductive portion of a printed circuit board. Overlayer **170** may be deposited doped polysilicon for a semiconductor substrate **150**, or copper for a printed circuit board substrate.

FIG. **7C-2** depicts a slot antenna version of what was shown in FIG. **7C-2**, wherein the conductive portion **170** (shown cross-hatched in FIG. **7C-2**) surrounds and defines a fractal-shape of non-conductive substrate **150**. Electrical connection to the slot antenna is made with a coaxial or other cable **50**, whose inner and outer conductors make contact as shown.

In FIGS. **7C-1** and **7C-2**, the substrate or plastic-like material in such constructions can contribute a dielectric effect that may alter somewhat the performance of a fractal antenna by reducing resonant frequency, which increases perimeter compression PC.

Those skilled in the art will appreciate that by virtue of the relatively large amount of conducting material (as contrasted to a thin wire), antenna efficiency is promoted in a slot configuration. Of course a printed circuit board or substrate-type construction could be used to implement a non-slot fractal antenna, e.g, in which the fractal motif is fabricated as a conductive trace and the remainder of the conductive material is etched away or otherwise removed. Thus, in FIG. **7C-1**, for example, if the cross-hatched surface now represents non-conductive material, and the non-cross hatched material represents conductive material, a printed circuit board or substrate-implemented wire-type fractal antenna results.

Printed circuit board and/or substrate-implemented fractal antennas are especially useful at frequencies of 80 MHz or higher, whereat fractal dimensions indeed become small. A 2 M MI-3 fractal antenna (e.g., FIG. **7E**) will measure about 5.5" (14 cm) on a side KS, and an MI-2 fractal antenna (e.g., FIG. **5B**) will be about 7" (17.5 cm) per side KS. As will be seen from FIG. **9A**, an MI-3 antenna suffers a slight loss in gain relative to an MI-2 antenna, but offers substantial size reduction.

Applicant has fabricated an MI-2 Minkowski island fractal antenna for operation in the 850–900 MHz cellular telephone band. The antenna was fabricated on a printed circuit board and measured about 1.2" (3 cm) on a side KS. The antenna was sufficiently small to fit inside applicant's cellular telephone, and performed as well as if the normal attachable "rubber-ducky" whip antenna were still attached. The antenna was found on the side to obtain desired vertical polarization, but could be fed anywhere on the element with 50 Ω impedance still being inherently present. Applicant also fabricated on a printed circuit board an MI-3 Minkowski island fractal quad, whose side dimension KS was about 0.8" (2 cm), the antenna again being inserted inside the cellular telephone. The MI-3 antenna appeared to work as well as the normal whip antenna, which was not attached. Again, any slight gain loss in going from MI-2 to MI-3 (e.g., perhaps 1 dB loss relative to an MI-0 reference quad, or 3 dB los relative to an MI-2) is more than offset by the resultant shrinkage in size. At satellite telephone frequencies of 1650 MHz or so, the dimensions would be approximately halved again. FIGS. **8**A, **8**B and **8**C depict preferred embodiments for such antennas.

FIG. **7D** depicts a 2 M dendrite deterministic fractal antenna that includes a slight amount of randomness. The vertical arrays of numbers depict wavelengths relative to 0λ, at the lower end of the trunk-like element **200**. Eight radial-like elements **210** are disposed at 1.0λ, and various other elements are disposed vertically in a plane along the length of element **200**. The antenna was fabricated using 12 gauge copper wire and was found to exhibit a surprising 20 dBi gain, which is at least 10 dB better than any antenna twice the size of what is shown in FIG. **7D**. Although superficially the vertical of FIG. **7D** may appear analogous to a log-periodic antenna, a fractal vertical according to the present invention does not rely upon an opening angle, in stark contrast to prior art log periodic designs.

FIG. **7E** depicts a third iteration Minkowski island quad antenna (denoted herein as MI-3). The orthogonal line segments associated with the rectangular Minkowski motif make this configuration especially acceptable to numerical study using ELNEC and other numerical tools using moments for estimating power patterns, among other modelling schemes. In testing various fractal antennas, applicant formed the opinion that the right angles present in the Minkowski motif are especially suitable for electromagnetic frequencies.

With respect to the MI-3 fractal of FIG. **7E**, applicant discovered that the antenna becomes a vertical if the center led of coaxial cable **50** is connected anywhere to the fractal, but the outer coaxial braid-shield is left unconnected at the antenna end. (At the transceiver end, the outer shield is connected to ground.) Not only do fractal antenna islands perform as vertical antennas when the center conductor of cable **50** is attached to but one side of the island and the braid is left ungrounded at the antenna, but resonance frequencies for the antenna so coupled are substantially reduced. For example, a 2" (5 cm) sized MI-3 fractal antenna resonated at 70 MHz when so coupled, which is equivalent to a perimeter compression PC≈20.

FIG. **7F** depicts a second iteration Koch fractal dipole, and FIG. **7G** a third iteration dipole. FIG. **7H** depicts a second iteration Minkowski fractal dipole, and FIG. **7I** a third iteration multi-fractal dipole. Depending upon the frequencies of interest, these antennas may be fabricated by bending wire, or by etching or otherwise forming traces on a substrate. Each of these dipoles provides substantially 50 Ω termination impedance to which coaxial cable **50** may be directly coupled without any impedance matching device. It is understood in these figures that the center conductor of cable **50** is attached to one side of the fractal dipole, and the braid outer shield to the other side.

FIG. **8**A depicts a generalized system in which a transceiver **500** is coupled to a fractal antenna system **510** to send electromagnetic radiation **520** and/or receive electromagnetic radiation **540**. A second transceiver **600** shown equipped with a conventional whip-like vertical antenna **610** also sends electromagnetic energy **630** and/or receives electromagnetic energy **540**.

If transceivers **500, 600** are communication devices such as transmitter-receivers, wireless telephones, pagers, or the like, a communications repeating unit such as a satellite **650** and/or a ground base repeater unit **660** coupled to an antenna **670**, or indeed to a fractal antenna according to the present invention, may be present.

Alteratively, antenna **510** in transceiver **500** could be a passive LC resonator fabricated on an integrated circuit microchip, or other similarly small sized substrate, attached to a valuable item to be protected. Transceiver **600**, or indeed unit **660** would then be an electromagnetic transmitter outputting energy at the frequency of resonance, a unit typically located near the cash register checkout area of a store or at an exit.

Depending upon whether fractal antenna-resonator **510** is designed to "blow" (e.g., become open circuit) or to "short" (e.g., become a close circuit) in the transceiver **500** will or will not reflect back electromagnetic energy **540** or **630** to a receiver associated with transceiver **600**. In this fashion, the unauthorized relocation of antenna **510** and/or transceiver **500** can be signalled by transceiver **600**.

FIG. **8**B depicts a transceiver **500** equipped with a plurality of fractal antennas, here shown as **510**A, **510**B, **510**C coupled by respective cables **50**A, **50**B, **50**C to electronics **600** within unit **500**. In the embodiment shown, the antennas are fabricated on a conformal, flexible substrate **150**, e.g., Mylar™ material or the like, upon which the antennas per se may be implemented by printing fractal patterns using conductive ink, by copper deposition, among other methods including printed circuit board and semiconductor fabrication techniques. A flexible such substrate may be conformed to a rectangular, cylindrical or other shape as necessary.

In the embodiment of FIG. **8**B, unit **500** is a handheld transceiver, and antennas **510**A, **510**B, **510**C preferably are fed for vertical polarization, as shown. An electronic circuit **610** is coupled by cables **50**A, **50**B, **50**C to the antennas, and samples incoming signals to discern which fractal antenna, e.g., **510**A, **510**B, **510**C is presently most optimally aligned with the transmitting station, perhaps a unit **600** or **650** or **660** as shown in FIG. **8**A. This determination may be made by examining signal strength from each of the antennas. An electronic circuit **620** then selects the presently best oriented antenna, and couples such antenna to the input of the receiver and output of the transmitter portion, collectively **630**, of unit **500**. It is understood that the selection of the best antenna is dynamic and can change as, for example, a user of **500** perhaps walks about holding the unit, or the transmitting source moves, or due to other changing conditions. In a cellular or a wireless telephone application, the result is more reliable communication, with the advantage that the fractal antennas can be sufficiently small-sized as to fit totally within the casing of unit **500**. Further, if a flexible substrate is used, the antennas may be wrapped about portions of the internal casing, as shown.

An additional advantage of the embodiment of FIG. **8**B is that the user of unit **500** may be physically distanced from the antennas by a greater distance that if a conventional external whip antenna were used. Although medical evidence attempting to link cancer with exposure to electromagnetic radiation from handheld transceivers is still inconclusive, the embodiment of FIG. **8**B appears to minimize any such risk.

FIG. **8**C depicts yet another embodiment wherein some or all of the antenna systems **510**A, **510**B, **510**C may include electronically steerable arrays, including arrays of fractal antennas of differing sizes and polarization orientations. Antenna system **510**C, for example may include similarly designed fractal antennas, e.g., antenna F-**3** and F-**4**, which are differently oriented from each other. Other antennas within system **510**C may be different in design from either of F-**3**, F-**4**. Fractal antenna F-**1** may be a dipole for example. Leads from the various antennas in system **510**C may be coupled to an integrated circuit **690**, mounted on substrate **150**. Circuit **690** can determine relative optimum choice between the antennas comprising system **510**C, and output via cable **50**C to electronics **600** associated with the transmitter and/or receiver portion of unit **630**.

Another antenna system **510**B may include a steerable array of identical fractal antennas, including fractal antenna F-**5** and F-**6**. An integrated circuit **690** is coupled to each of the antennas in the array, and dynamically selects the best antenna for signal strength and coupled such antenna via cable **50**B to electronics **600**. A third antenna system **510**A may be different from or identical to either of system **510**B and **510**C.

Although FIG. **8**C depicts a unit **500** that may be handheld, unit **500** could in fact be a communications system for use on a desk or a field mountable unit, perhaps unit **660** as shown in FIG. **8**A.

For ease of antenna matching to a transceiver load, resonance of a fractal antenna was defined as a total impedance falling between about 20 Ω to 200 Ω, and the antenna was required to exhibit medium to high Q, e.g., frequency/Δfrequency. In practice, applicants' various fractal antennas were found to resonate in at least one position of the antenna feedpoint, e.g., the point at which coupling was made to the antenna. Further, multi-iteration fractals according to the present invention were found to resonate at multiple frequencies, including frequencies that were non-harmonically related.

Contrary to conventional wisdom, applicant found that island-shaped fractals (e.g., a closed loop-like configuration) do not exhibit significant drops in radiation resistance R for decreasing antenna size. As described herein, fractal antennas were constructed with dimensions of less than 12" across (30.48 cm) and yet resonated in a desired 60 MHz to 100 MHz frequency band.

Applicant further discovered that antenna perimeters do not correspond to lengths that would be anticipated from measured resonant frequencies, with actual lengths being longer than expected. This increase in element length appears to be a property of fractals as radiators, and not a result of geometric construction. A similar lengthening effect was reported by Pfeiffer when constructing a full-sized quad antenna using a first order fractal, see A. Pfeiffer, *The Pfeiffer Quad Antenna System,* QST, p. 28–32 (March 1994).

If L is the total initial one-dimensional length of a fractal pre-motif application, and r is the one-dimensional length post-motif application, the resultant fractal dimension D (actually a ratio limit) is:

$$D=\log(L)/\log(r)$$

With reference to FIG. **1**A, for example, the length of FIG. **1**A represents L, whereas the sum of the four line segments comprising the Koch fractal of FIG. **1**B represents r.

Unlike mathematical fractals, fractal antennas are not characterized solely by the ratio D. In practice D is not a good predictor of how much smaller a fractal design antenna may be because D does not incorporate the perimeter lengthening of an antenna radiating element.

Because D is not an especially useful predictive parameter in fractal antenna design, a new parameter "perimeter compression" ("PC") shall be used, where:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

In the above equation, measurements are made at the fractal-resonating element's lowest resonant frequency. Thus, for a full-sized antenna according to the prior art PC=1, while PC=3 represents a fractal antenna according to the present invention, in which an element side has been reduced by a factor of three.

Perimeter compression may be empirically represented using the fractal dimension D as follows:

$$PC = A \cdot \log[N(D+C)]$$

where A and C are constant coefficients for a given fractal motif, N is an iteration number, and D is the fractal dimension, defined above.

It is seen that for each fractal, PC becomes asymptotic to a real number and yet does not approach infinity even as the iteration number N becomes very large. Stated differently, the PC of a fractal radiator asymptotically approaches a non-infinite limit in a finite number of fractal iterations. This result is not a representation of a purely geometric fractal.

That some fractals are better resonating elements than other fractals follows because optimized fractal antennas approach their asymptotic PCs in fewer iterations than non-optimized fractal antennas. Thus, better fractals for antennas will have large values for A and C, and will provide the greatest and most rapid element-size shrinkage. Fractal used may be deterministic or chaotic. Deterministic fractals have a motif that replicates at a 100% level on all size scales, whereas chaotic fractals include a random noise component.

Applicant found that radiation resistance of a fractal antenna decreases as a small power of the perimeter compression (PC), with a fractal island always exhibiting a substantially higher radiation resistance than a small Euclidean loop antenna of equal size.

Further, it appears that the number of resonant nodes of a fractal island increase as the iteration number (N) and is always greater than or equal to the number of resonant nodes of an Euclidean island with the same area.

Finally, it appears that a fractal resonator has an increased effective wavelength.

The above findings will now be applied to experiments conducted by applicant with fractal resonators shaped into closed-loops or islands. Prior art antenna analysis would predict no resonance points, but as shown below, such is not the case.

A Minkowski motif is depicted in FIGS. **2B–2D**, **5B**, **7C** and **7E**. The Minkowski motif selected was a three-sided box (e.g., **20-2** in FIG. **2B**) placed atop a line segment. The box sides may be any arbitrary length, e.g, perhaps a box height and width of 2 units with the two remaining base sides being of length three units (see FIG. **2B**). For such a configuration, the fractal dimension D is as follows:

$$D = \frac{\log(L)}{\log(r)} = \frac{\log(12)}{\log(8)} = \frac{1.08}{0.90} = 1.20$$

It will be appreciated that D=1.2 is not especially high when compared to other deterministic fractals.

Applying the motif to the line segment may be most simply expressed by a piecewise function f(x) as follows:

$$\begin{aligned} f(x) &= 0 && 0 \geq x \geq \frac{3x_{\max}}{8} \\ f(x) &= \frac{1}{4x_{\max}} && \frac{3x_{\max}}{8} \geq x \geq \frac{5x_{\max}}{8} \\ f(x) &= 0 && \frac{5x_{\max}}{8} \geq x \geq x_{\max} \end{aligned}$$

where x_{max} is the largest continuous value of x on the line segment.

A second iteration may be expressed as $f(x)_2$ relative to the first iteration $f(x)_1$ by:

$$f(x)_2 = f(x)_1 + f(x)$$

where x_{max} is defined in the above-noted piecewise function. Note that each separate horizontal line segment will have a different lower value of x and x_{max}. Relevant offsets from zero may be entered as needed, and vertical segments may be "boxed" by 90° rotation and application of the above methodology.

As shown by FIGS. **5B** and **7E**, a Minkowski fractal quickly begins to appear like a Moorish design pattern. However, each successive iteration consumes more perimeter, thus reducing the overall length of an orthogonal line segment. Four box or rectangle-like fractals of the same iteration number N may be combined to create a Minkowski fractal island, and a resultant "fractalized" cubical quad.

An ELNEC simulation was used as a guide to far-field power patterns, resonant frequencies, and SWRs of Minkowski Island fractal antennas up to iteration N=2. Analysis for N>2 was not undertaken due to inadequacies in the test equipment available to applicant.

The following tables summarize applicant's ELNEC simulated fractal antenna designs undertaken to derive lowest frequency resonances and power patterns, to and including iteration N=2. All designs were constructed on the x,y axis, and for each iteration the outer length was maintained at 42" (106.7 cm).

Table 1, below, summarizes ELNEC-derived far field radiation patterns for Minkowski island quad antennas for each iteration for the first four resonances. In Table 1, each iteration is designed as MI-N for Minkowski Island of iteration N. Note that the frequency of lowest resonance decreased with the fractal Minkowski Island antennas, as compared to a prior art quad antenna. Stated differently, for a given resonant frequency, a fractal Minkowski Island antenna will be smaller than a conventional quad antenna.

TABLE 1

Antenna	Res. Freq. (MHz)	Gain (dBi)	SWR	PC (for 1st)	Direction
Ref. Quad	76	3.3	2.5	1	Broadside
	144	2.8	5.3	—	Endfire

TABLE 1-continued

Antenna	Res. Freq. (MHz)	Gain (dBi)	SWR	PC (for 1st)	Direction
	220	3.1	5.2	—	Endfire
	294	5.4	4.5	—	Endfire
MI-1	55	2.6	1.1	1.38	Broadside
	101	3.7	1.4	—	Endfire
	142	3.5	5.5	—	Endfire
	198	2.7	3.3	—	Broadside
MI-2	43.2	2.1	1.5	1.79	Broadside
	85.5	4.3	1.8	—	Endfire
	102	2.7	4.0	—	Endfire
	116	1.4	5.4	—	Broadside

It is apparent from Table 1 that Minkowski island fractal antennas are multi-resonant structures having virtually the same gain as larger, full-sized conventional quad antennas. Gain figures in Table 1 are for "free-space" in the absence of any ground plane, but simulations over a perfect ground at 1λ yielded similar gain results. Understandably, there will be some inaccuracy in the ELNEC results due to round-off and undersampling of pulses, among other factors.

Table 2 presents the ratio of resonant ELNEC-derived frequencies for the first four resonance nodes referred to in Table 1.

TABLE 2

Antenna	SWR	SWR	SWR	SWR
Ref. Quad (MI-0)	1:1	1:1.89	1:2.89	3.86:1
MI-1	1:1	1:1.83	1:2.58	3.6:1
MI-2	1:1	2.02:1	2.41:1	2.74:1

Tables 1 and 2 confirm the shrinking of a fractal-designed antenna, and the increase in the number of resonance points. In the above simulations, the fractal MI-2 antenna exhibited four resonance nodes before the prior art reference quad exhibited its second resonance. Near fields in antennas are very important, as they are combined in multiple-element antennas to achieve high gain arrays. Unfortunately, programming limitations inherent in ELNEC preclude serious near field investigation. However, as described later herein, applicant has designed and constructed several different high gain fractal arrays that exploit the near field.

Applicant fabricated three Minkowski Island fractal antennas from aluminum #8 and/or thinner #12 galvanized groundwire. The antennas were designed so the lowest operating frequency fell close to a desired frequency in the 2 M (144 MHz) amateur radio band to facilitate relative gain measurements using 2 M FM repeater stations. The antennas were mounted for vertical polarization and placed so their center points were the highest practical point above the mounting platform. For gain comparisons, a vertical ground plane having three reference radials, and a reference quad were constructed, using the same sized wire as the fractal antenna being tested. Measurements were made in the receiving mode.

Multi-path reception was minimized by careful placement of the antennas. Low height effects were reduced and free space testing approximated by mounting the antenna test platform at the edge of a third-store window, affording a 3.5λ height above ground, and line of sight to the repeater, 45 miles (28 kM) distant. The antennas were stuck out of the window about 0.8λ from any metallic objects and testing was repeated on five occasions from different windows on the same floor, with test results being consistent within ½ dB for each trial.

Each antenna was attached to a short piece of 9913 50 Ω coaxial cable, fed at right angles to the antenna. A 2 M transceiver was coupled with 9913 coaxial cable to two precision attenuators to the antenna under test. The transceiver S-meter was coupled to a volt-ohm meter to provide signal strength measurements The attenuators were used to insert initial threshold to avoid problems associated with non-linear S-meter readings, and with S-meter saturation in the presence of full squelch quieting.

Each antenna was quickly switched in for volt-ohmmeter measurement, with attenuation added or subtracted to obtain the same meter reading as experienced with the reference quad. All readings were corrected for SWR attenuation. For the reference quad, the SWR was 2.4:1 for 120 Ω impedance, and for the fractal quad antennas SWR was less than 1.5:1 at resonance. The lack of a suitable noise bridge for 2 M precluded efficiency measurements for the various antennas. Understandably, anechoic chamber testing would provide even more useful measurements.

For each antenna, relative forward gain and optimized physical orientation were measured. No attempt was made to correct for launch-angle, or to measure power patterns other than to demonstrate the broadside nature of the gain. Difference of ½ dB produced noticeable S-meter deflections, and differences of several dB produced substantial meter deflection. Removal of the antenna from the receiver resulted in a 20^{+}dB drop in received signal strength. In this fashion, system distortions in readings were cancelled out to provide more meaningful results. Table 3 summarizes these results.

TABLE 3

Antenna	PC	PL	SWR	Cor. Gain (dB)	Sidelength (λ)
Quad	1	1	2.4:1	0	0.25
¼ wave	1	—	1.5:1	−1.5	0.25
MI-1	1.3	1.2	1.3:1	1.5	0.13
MI-2	1.9	1.4	1.3:1	1.5	0.13
MI-3	2.4	1.7	1:1	−1.2	0.10

It is apparent from Table 3 that for the vertical configurations under test, a fractal quad according to the present invention either exceeded the gain of the prior art test quad, or had a gain deviation of not more than 1 dB from the test quad. Clearly, prior art cubical (square) quad antennas are not optimized for gain. Fractally shrinking a cubical quad by a factor of two will increase the gain, and further shrinking will exhibit modest losses of 1–2 dB.

Versions of a MI-2 and MI-3 fractal quad antennas were constructed for the 6 M (50 MHz) radio amateur band. An RX 50 Ω noise bridge was attached between these antennas and a transceiver. The receiver was nulled at about 54 MHz and the noise bridge was calibrated with 5 Ω and 10 Ω resistors. Table 4 below summarizes the results, in which almost no reactance was seen.

TABLE 4

Antenna	SWR	Z (Ω)	O (Ω)	E (%)
Quad (MI-0)	2.4:1	120	5–10	92–96
MI-2	1.2:1	60	≦5	≧92
MI-3	1.1:1	55	≦5	≧91

In Table 4, efficiency (E) was defined as 100%*(R/Z), where Z was the measured impedance, and R was Z minus ohmic impedance and reactive impedances (0). As shown in Table 4, fractal MI-2 and MI-3 antennas with their low

≦1.2:1 SWR and low ohmic and reactive impedance provide extremely high efficiencies, $90^{+}\%$. These findings are indeed surprising in view of prior art teachings stemming from early Euclidean small loop geometries. In fact, Table 4 strongly suggests that prior art associations of low radiation impedances for small loops must be abandoned in general, to be invoked only when discussing small Euclidean loops. Applicant's MI-3 antenna was indeed micro-sized, being dimensioned at about 0.1λ per side, an area of about $\lambda^2/1{,}000$, and yet did not signal the onset of inefficiency long thought to accompany smaller sized antennas.

However the 6M efficiency data do not explain the fact that the MI-3 fractal antenna had a gain drop of almost 3 dB relative to the MI-2 fractal antenna. The low ohmic impedances of ≦5 Ω strongly suggest that the explanation is other than inefficiency, small antenna size notwithstanding. It is quite possible that near field diffraction effects occur at higher iterations that result in gain loss. However, the smaller antenna sizes achieved by higher iterations appear to warrant the small loss in gain.

Using fractal techniques, however, 2 M quad antennas dimensioned smaller than 3" (7.6 cm) on a side, as well as 20 M (14 MHz) quads smaller than 3' (1 m) on a side can be realized. Economically of greater interest, fractal antennas constructed for cellular telephone frequencies (850 MHz) could be sized smaller than 0.5" (1.2 cm). As shown by FIGS. **8**B and **8**C, several such antenna, each oriented differently could be fabricated within the curved or rectilinear case of a cellular or wireless telephone, with the antenna outputs coupled to a circuit for coupling to the most optimally directed of the antennas for the signal then being received. The resultant antenna system would be smaller than the "rubber-ducky" type antennas now used by cellular telephones, but would have improved characteristics as well.

Similarly, fractal-designed antennas could be used in handheld military walkie-talkie transceivers, global positioning systems, satellites, transponders, wireless communication and computer networks, remote and/or robotic control systems, among other applications.

Although the fractal Minkowski island antenna has been described herein, other fractal motifs are also useful, as well as non-island fractal configurations.

Table 5 demonstrates bandwidths ("BW") and multi-frequency resonances of the MI-2 and MI-3 antennas described, as well as Qs, for each node found for 6 M versions between 30 MHz and 175 MHz. Irrespective of resonant frequency SWR, the bandwidths shown are SWR 3:1 values. Q values shown were estimated by dividing resonant frequency by the 3:1 SWR BW. Frequency ratio is the relative scaling of resonance nodes.

TABLE 5

Antenna	Freq. (MHz)	Freq. Ratio	SWR	3:1 BW	Q
MI-3	53.0	1	1:1	6.4	8.3
	80.1	1.5:1	1.1:1	4.5	17.8
	121.0	2.3:1	2.4:1	6.8	17.7
MI-2	54.0	1	1:1	3.6	15.0
	95.8	1.8:1	1.1:1	7.3	13.1
	126.5	2.3:1	2.4:1	9.4	13.4

The Q values in Table 5 reflect that MI-2 and MI-3 fractal antennas are multiband. These antennas do not display the very high Qs seen in small tuned Euclidean loops, and there appears not to exist a mathematical application to electromagnetics for predicting these resonances or Qs. One approach might be to estimate scalar and vector potentials in Maxwell's equations by regarding each Minkowski Island iteration as a series of vertical and horizontal line segments with offset positions. Summation of these segments will lead to a Poynting vector calculation and power pattern that may be especially useful in better predicting fractal antenna characteristics and optimized shapes.

In practice, actual Minkowski Island fractal antennas seem to perform slightly better than their ELNEC predictions, most likely due to inconsistencies in ELNEC modelling or ratios of resonant frequencies, PCs, SWRs and gains.

Those skilled in the art will appreciate that fractal multiband antenna arrays may also be constructed. The resultant arrays will be smaller than their Euclidean counterparts, will present less wind area, and will be mechanically rotatable with a smaller antenna rotator.

Further, fractal antenna configurations using other than Minkowski islands or loops may be implemented. Table 6 shows the highest iteration number N for other fractal configurations that were found by applicant to resonant on at least one frequency.

TABLE 6

Fractal	Maximum Iteration

FIG. **9**A depicts gain relative to an Euclidean quad (e.g., an MI-0) configuration as a function of iteration value N. (It is understood that an Euclidean quad exhibits 1.5 dB gain relative to a standard reference dipole.) For first and second order iterations, the gain of a fractal quad increases relative to an Euclidean quad. However, beyond second order, gain drops off relative to an Euclidean quad. Applicant believes that near field electromagnetic energy diffraction-type cancellations may account for the gain loss for N>2. Possibly the far smaller areas found in fractal antennas according to the present invention bring this diffraction phenomenon into sharper focus.

n practice, applicant could not physically bend wire for a 4th or 5th iteration 2 M Minkowski fractal antenna, although at lower frequencies the larger antenna sizes would not present this problem. However, at higher frequencies, printed circuitry techniques, semiconductor fabrication techniques as well as machine-construction could readily produce N=4, N=5, and higher order iterations fractal antennas.

In practice, a Minkowski island fractal antenna should reach the theoretical gain limit of about 1.7 dB seen for sub-wavelength Euclidean loops, but N will be higher than 3. Conservatively, however, an N=4 Minkowski Island fractal quad antenna should provide a PC=3 value without exhibiting substantial inefficiency.

FIG. **9**B depicts perimeter compression (PC) as a function of iteration order N for a Minkowski island fractal configuration. A conventional Euclidean quad (MI-0) has PC=1 (e.g., no compression), and as iteration increases, PC increases. Note that as N increases and approaches 6, PC approaches a finite real number asymptotically, as predicted. Thus, fractal Minkowski Island antennas beyond iteration N=6 may exhibit diminishing returns for the increase in iteration.

It will be appreciated that the non-harmonic resonant frequency characteristic of a fractal antenna according to the present invention may be used in a system in which the frequency signature of the antenna must be recognized to pass a security test. For example, at suitably high frequencies, perhaps several hundred MHz, a fractal antenna could be implemented within an identification credit card. When the card is used, a transmitter associated with a credit card reader can electronically sample the frequency resonance of the antenna within the credit card. If and only if the credit card antenna responds with the appropriate frequency signature pattern expected may the credit card be used, e.g., for purchase or to permit the owner entrance into an otherwise secured area.

FIG. **10**A depicts a fractal inductor L according to the present invention. In contrast to a prior art inductor, the winding or traces with which L is fabricated define, at least in part, a fractal. The resultant inductor is physically smaller than its Euclidean counterpart. Inductor L may be used to form a resonator, including resonators such as shown in FIGS. **4**A and **4**B. As such, an integrated circuit or other suitably small package including fractal resonators could be used as part of a security system in which electromagnetic radiation, perhaps from transmitter **600** or **660** in FIG. **8**A will blow, or perhaps not blow, an LC resonator circuit containing the fractal antenna. Such applications are described elsewhere herein and may include a credit card sized unit **700**, as shown in FIG. **10**B, in which an LC fractal resonator **710** is implemented. (Card **700** is depicted in FIG. **10**B as though its upper surface were transparent.)

The foregoing description has largely replicated what has been set forth in applicant's above-noted FRACTAL ANTENNAS AND FRACTAL RESONATORS patent application. The following section will set forth methods and techniques for tuning such fractal antennas and resonators. In the following description, although the expression "antenna" may be used in referring to a preferably fractal element, in practice what is being described is an antenna or filter-resonator system. As such, an "antenna" can be made to behave as through it were a filter, e.g., passing certain frequencies and rejecting other frequencies (or the converse).

In one group of embodiments, applicant has discovered that disposing a fractal antenna a distance Δ that is in close proximity (e.g., less than about 0.05λ for the frequency of interest) from a conductor advantageously can change the resonant properties and radiation characteristics of the antenna (relative to such properties and characteristics when such close proximity does not exist, e.g., when the spaced-apart distance is relatively great. For example, in FIG. **11**A a conductive surface **800** is disposed a distance Δ behind or beneath a fractal antenna **810**, which in FIG. **11**A is a single arm of an MI-2 fractal antenna. Of course other fractal configurations such as disclosed herein could be used instead of the MI-1 configuration shown, and non-planar configurations may also be used. Fractal antenna **810** preferably is fed with coaxial cable feedline **50**, whose center conductor is attached to one end **815** of the fractal antenna, and whose outer shield is grounded to the conductive plane **800**. As described herein, great flexibility in connecting the antenna system shown to a preferably coaxial feedline exists. Termination impedance is approximately of similar magnitudes as described earlier herein.

In the configuration shown, the relative close proximity between conductive sheet **800** and fractal antenna **810** lowers the resonant frequencies and widens the bandwidth of antenna **810**. The conductive sheet **800** may be a plane of metal, the upper copper surface of a printed circuit board, a region of conductive material perhaps sprayed onto the housing of a device employing the antenna, for example the interior of a transceiver housing **500**, such as shown in FIGS. **8**A, **8**B, **8**C, and **15**.

The relationship between Δ, wherein $\Delta \leqq 0.05\lambda$, and resonant properties and radiation characteristics of a fractal antenna system is generally logarithmic. That is, resonant frequency decreases logarithmically with decreasing separation Δ.

FIG. **11**B shows an embodiment in which a preferably fractal antenna **810** lies in the same plane as a ground plane **800** but is separated therefrom by an insulating region, and in which a passive or parasitic element **800'** is disposed "within" and spaced-apart a distance Δ' from the antenna, and also being coplanar. For example, the embodiment of FIG. **11**B may be fabricated from a single piece of printed circuit board material in which copper (or other conductive material) remains to define the groundplane **800**, the antenna **810**, and the parasitic element **800'**, the remaining portions of the original material having been etched away to form the "moat-like" regions separating regions **800**, **810**, and **800'**. Changing the shape and/or size of element **800'** and/or the coplanar spaced-apart distance Δ' tunes the antenna system shown. For example, for a center frequency in the 900 MHz range, element **800'** measured about 63 mm×8 mm, and elements **810** and **800** each measured about 25 mm×12 mm. In general, element **800** should be at least as large as the preferably fractal antenna **810**. For this configuration, the system shown exhibited a bandwidth of about 200 MHz, and could be made to exhibit characteristics of a bandpass filter and/or band rejection filter. In this embodiment, a coaxial feedline **50** was used, in which the center lead was coupled to antenna **810**, and the ground shield lead was coupled to groundplane **800**. In FIG. **11**B, the inner perimeter of groundplane region **800** is shown as being rectangularly shaped. If desired, this inner perimeter could be moved closer to the outer perimeter of preferably fractal antenna **810**, and could in fact define a perimeter shape that follows the perimeter shape of antenna **810**. In such an embodiment, the perimeter of the inner conductive region **800'** and the inner perimeter of the ground plane region **800** would each follow the shape of antenna **810**. Based upon experiments to date, it is applicant's belief that moving the inner perimeter of ground plane region **800** sufficiently close to antenna **810** could also affect the characteristics of the overall antenna/resonator system.

Referring now to FIG. **12**A, if the conductive surface **800** is replaced with a second fractal antenna **810'**, which is spaced-apart a distance Δ that preferably does not exceed about 0.05λ, resonances for the radiating fractal antenna **810** are lowered and advantageously new resonant frequencies emerge. For ease of fabrication, it may be desired to construct antenna **810** on the upper or first surface **820**A of a substrate **820**, and to construct antenna **810'** on the lower or second surface **820**B of the same substrate. The substrate could be doubled-side printed circuit board type material, if desired, wherein antennas **810**, **810'** are fabricated using printed circuit type techniques. The substrate thickness Δ is selected to provide the desired performance for antenna **810** at the frequency of interest. Substrate **820** may, for example, be a non-conductive film, flexible or otherwise. To avoid cluttering FIGS. **12**A and **12**B, substrate **820** is drawn with phantom lines, as if the substrate were transparent.

Preferably, the center conductor of coaxial cable **50** is connected to one end **815** of antenna **810**, and the outer conductor of cable **50** is connected to a free end **815'** of antenna **810**', which is regarded as ground, although other feedline connections may be used. Although FIG. **12**A depicts antenna **810**' as being substantially identical to antenna **810**, the two antennas could in fact have different configurations.

Applicant has discovered that if the second antenna **810**' is rotated some angle θ relative to antenna **810**, the resonant frequencies of antenna **810** may be varied, analogously to tuning a variable capacitor. Thus, in FIG. **12**B, antenna **810** is tuned by rotating antenna **810**' relative to antenna **810** (or the converse, or by rotating each antenna). If desired, substrate **820** could comprise two substrates each having thickness Δ/2 and pivotally connected together, e.g., with a non-conductive rivet, so as to permit rotation of the substrates and thus relative rotation of the two antennas. Those skilled in the mechanical arts will appreciate that a variety of "tuning" mechanisms could be implemented to permit fine control over the angle θ in response, for example, to rotation of a tunable shaft.

Referring now to FIG. **13**A, applicant has discovered that creating at least one cut or opening **830** in a fractal antenna **810** (here comprising two legs of an MI-2 antenna) results in new and entirely different resonant nodes for the antenna. Further, these nodes can have perimeter compression (PC) ranging from perhaps three to about ten. The precise location of cut **830** on the fractal antenna or resonator does not appear to be critical.

FIGS. **13**B and **13**C depict a self-proximity characteristic of fractal antennas and resonators that may advantageously be used to create a desired frequency resonant shift. In FIG. **13**B, a fractal antenna **810** is fabricated on a first surface **820**A of a flexible substrate **820**, whose second surface **820**B does not contain an antenna or other conductor in this embodiment. Curving substrate **820**, which may be a flexible film, appears to cause electromagnetic fields associated with antenna **810** to be sufficiently in self-proximity so as to shift resonant frequencies. Such self-proximity antennas or resonators may be referred to a com-cyl devices. The extent of curvature may be controlled where a flexible substrate or substrate-less fractal antenna and/or conductive element is present, to control or tune frequency dependent characteristics of the resultant system. Com-cyl embodiments could include a concentrically or eccentrically disposed fractal antenna and conductive element. Such embodiments may include telescopic elements, whose extent of "overlap" may be telescopically adjusted by contracting or lengthening the overall configuration to tune the characteristics of the resultant system. Further, more than two elements could be provided.

In FIG. **13**C, a fractal antenna **810** is formed on the outer surface **820**A of a filled substrate **820**, which may be a ferrite core. The resultant com-cyl antenna appears to exhibit self-proximity such that desired shifts in resonant frequency are produced. The geometry of the core **820**, e.g., the extent of curvature (e.g., radius in this embodiment) relative to the size of antenna **810** may be used to determine frequency shifts.

In FIG. **14**A, an antenna or resonator system is shown in which the non-driven fractal antenna **810**' is not connected to the preferably coaxial feedline **50**. The ground shield portion of feedline **50** is coupled to the groundplane conductive element **800**, but is not otherwise connected to a system ground. Of course fractal antenna **810**' could be angularly rotated relative to driven antenna **810**, it could be a different configuration than antenna **810** including having a different iteration N, and indeed could incorporate other features disclosed herein (e.g., a cut).

FIG. **14**B demonstrates that the driven antenna **810** may be coupled to the feedline **50** at any point **815**', and not necessarily at an end point **815** as was shown in FIG. **14**A.

In the embodiment of FIG. **14**C, a second ground plane element **800**' is disposed adjacent at least a portion of the system comprising driven antenna **810**, passive antenna **810**', and the underlying conductive planar element **800**. The presence, location, geometry, and distance associated with second ground plane element **800**' from the underlying elements **810, 810', 800** permit tuning characteristics of the overall antenna or resonator system. In the multi-element sandwich-like configuration shown, the ground shield of conductor **50** is connected to a system ground but not to either ground plane **800** or **800**'. Of course more than three elements could be used to form a tunable system according to the present invention.

FIG. **14**D shows a single fractal antenna spaced apart from an underlying ground plane **800** a distance Δ, in which a region of antenna **800** is cutaway to increase resonance. In FIG. **14**D, for example, L1 denotes a cutline, denoting that portions of antenna **810** above (in the Figure drawn) L1 are cutaway and removed. So doing will increase the frequencies of resonance associated with the remaining antenna or resonator system. On the other hand, if portions of antenna **810** above cutline L2 are cutaway and removed, still higher resonances will result. Selectively cutting or etching away portions of antenna **810** permit tuning characteristics of the remaining system.

FIG. **15** depicts an embodiment somewhat similar to what has been described with respect to FIG. **8**B or FIG. **8**C. Once again unit **500** is a handheld transceiver, and includes fractal antennas **510**A, **510**B–**510**B', **510**C. Antennas **510**B–**510**B' are similar to what has been described with respect to FIGS. **12**A–**12**B. Antennas **510**B–**510**B' are fractal antennas, not necessarily MI-2 configuration as shown, and are spaced-apart a distance a and, in FIG. **13**, are rotationally displaced. Collectively, the spaced-apart distance and relative rotational displacement permits tuning the characteristics of the driven antenna, here antenna **510**B. In FIG. **14**, antenna **510**A is drawn with phantom lines to better distinguish it from spaced-apart antenna **510**B. Of course passive conductor **510**B' could instead be a solid conductor such as described with respect to FIG. **11**A. Such conductor may be implemented by spraying the inner surface of the housing for unit **500** adjacent antenna **510**B with conductive paint.

In FIG. **15**, antenna **510**C is similar to what has been described with respect to FIG. **13**A, in that a cut **830** is made in the antenna, for tuning purposes. Although antenna **510**A is shown similar to what was shown in FIG. **8**B, antenna **510**A could, if desired, be formed on a curved substrate similar to FIG. **13**B or **13**C. While FIGS. **13**A-**1**–**13**C and **14**C show at least two different techniques for tuning antennas according to the present invention, it will be understood that a common technique could instead be used. By that it is meant that any or all of antennas **510**A, **510**B–**510**B', **510**C could include a cut, or be spaced-apart a controllable distance Δ, or be rotatable relative to a spaced-apart conductor.

As described with respect to FIG. **8**B, an electronic circuit **615** may be coupled by cables **50**A, **50**B, **50**C to the antennas, and samples incoming signals to discern which fractal antenna, e.g., **510**A, **510**B–**510**B', **510**C is presently most optimally aligned with the transmitting station, perhaps a unit **600** or **650** or **660** as shown in FIG. **8**A. This determination may be made by examining signal strength from each of the antennas. An electronic circuit **620** then selects the presently best oriented antenna, and couples such antenna to the input of the receiver and output of the transmitter portion, collectively **630**, of unit **500**. It is understood that the selection of the best antenna is dynamic and can change as, for example, a user of **500** perhaps walks about holding the unit, or the transmitting source moves, or due to other changing conditions. In a cellular or a wireless telephone application, the result is more reliable communication, with the advantage that the fractal antennas can be sufficiently small-sized as to fit totally within the casing of unit **500**. Further, if a flexible substrate is used, the antennas may be wrapped about portions of the internal casing, as shown.

An additional advantage of the embodiment of FIG. **8**B is that the user of unit **500** may be physically distanced from the antennas by a greater distance that if a conventional external whip antenna were used. Although medical evidence attempting to link cancer with exposure to electromagnetic radiation from handheld transceivers is still inconclusive, the embodiment of FIG. **8**B appears to minimize any such risk.

Modifications and variations may be made to the disclosed embodiments without departing from the subject and spirit of the invention as defined by the following claims. While common fractal families include Koch, Minkowski, Julia, diffusion limited aggregates, fractal trees, Mandelbrot, the present invention may be practiced with other fractals as well.

What is claimed is:

1. An antenna system comprising:

a first fractal antenna including a first element having a portion that includes:

at least a first motif selected from a family consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot. (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia;

and a first replication of said first motif and a second replication of said first motif such that a point chosen on a geometric figure represented by said first motif will result in a corresponding point on said first replication and on said second replication of said first motif; wherein there exists at least one non-straight line locus connecting each said point;

wherein a replication of said first motif is a change selected from a group consisting of (a) a rotation and change of scale of said first motif, (b) a linear displacement translation and a change of scale of said first motif, and (c) a rotation and a linear displacement translation and a change of scale of said first motif, and wherein said first fractal antenna is characterized in space by at least one resonant frequency and by a bandwidth; and

a conductive element, spaced-apart from said first fractal antenna by a distance Δ chosen to vary at least one characteristic of said antenna system, at a desired frequency c/λ, where c is velocity of light, selected from a group consisting of (i) said resonant frequency, and (ii) said bandwidth.

2. The antenna system of claim **1**, wherein said distance Δ has at least one characteristic selected from a group consisting of (a) said first fractal antenna and said conductive element are spaced-apart in different planes by a distance $\Delta \leqq 0.05\lambda$ where λ is wavelength at a resonant frequency of said antenna system in free space, (b) said first fractal antenna and said conductive element are spaced-apart in a common plane by said distance Δ, and (c) at least one of said first fractal antenna and said conductive element is non-planar and said distance Δ defines a closest distance separating said first fractal antenna from said conductive element.

3. The antenna system of claim **1**, wherein said conductive element is selected from a group consisting of (a) a planar conductor, (b) a second fractal antenna defined by an iteration identical to said first fractal antenna, (c) a second fractal antenna defined by an iteration N identical to said first fractal antenna but having a different configuration, (d) a second fractal antenna defined by at least a third-order iteration, and (e) a second fractal antenna defined by at least a third-order iteration and having a configuration similar to a configuration of said first fractal antenna.

4. The antenna system of claim **1**, wherein said conductive element is a second fractal antenna that includes a second element having a portion that includes at least a second motif and a first replication of said second motif and a second replication of said second motif such that a point chosen on a geometric figure represented by said second motif will result in a corresponding point on said first replication and on said second replication of said second motif; wherein there exists at least one locus connecting each said point that does not define a straight line; and

wherein a replication of said second motif is a change selected from a group consisting of (a) a rotation and change of scale of said second motif, (b) a linear displacement translation and a change of scale of said second motif, and (c) a rotation and a linear displacement translation and a change of scale of said second motif;

wherein one of said first fractal antenna and said second fractal antenna is rotatable through a relative angle θ therebetween to vary at least one characteristic of said antenna system.

5. The antenna system of claim **1**, wherein said first fractal antenna includes a region that defines a cut such that at least one said resonant frequency of said antenna system is varied by said cut.

6. The antenna system of claim **1**, wherein said first fractal antenna is formed non-planarly to vary at least one said resonant frequency of said antenna system.

7. The antenna system of claim **1**, wherein said antenna system includes a ferrite core about which said first fractal antenna is formed.

8. The antenna system of claim **1**, further including a feedline having a center conductor and a ground conductor; wherein:

a portion of said first fractal antenna is connected to said center conductor of said feedline, and a portion of said conductive element is connected to said ground conductor of said feedline.

9. The antenna system of claim **4**, further including a feedline having a center conductor and a ground conductor; wherein:

a portion of said first fractal antenna is connected to said center conductor of said feedline, and said ground conductor of said feedline is connected to at least one region of said system defined by (a) a portion of said second fractal antenna, (b) a system ground, and (c) said conductive element and a system ground.

10. The antenna system of claim **1**, further including:

a ground plane member;

said ground member disposed sufficiently close to said first fractal antenna so as to vary a characteristic of said antenna system.

11. The antenna system of claim **1**, wherein said first motif has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, y_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates for iteration N, and where f(x,y) and g(x,y) are functions defining said first motif.

12. The antenna system of claim **1**, wherein said first fractal antenna has a perimeter compression parameter (PC) defined by:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC = A \cdot \log[N(D+C)]$$

in which A and C are constant coefficients for a given said first motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization, respectively.

13. A tunable fractal antenna system coupleable to a transceiver unit, the antenna comprising:

a first fractal antenna including:

a first element having a portion that includes at least a first motif selected from a family consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia;

and a first replication of said first motif and a second replication of said first motif such that a point chosen on a geometric figure represented by said first motif will result in a corresponding point on said first replication and on said second replication of said first motif; wherein there exists at least one non-straight line locus connecting each said point;

wherein a replication of said first motif is a change selected from a group consisting of (a) a rotation and change of scale of said first motif, (b) a linear displacement translation and a change of scale of said first motif, and (c) a rotation and a linear displacement translation and a change of scale of said first motif; and

a conductive element, spaced-apart from said first fractal antenna by a distance Δ chosen to vary at least one characteristic of said antenna system, at a desired frequency c/λ, where c is velocity of light, selected from the group consisting of (i) resonant frequency of said antenna system, and (ii) bandwidth of said antenna system.

14. The tunable fractal antenna system of claim **13**, wherein said conductive element is selected from a group consisting of (a) a planar conductor, (b) a second fractal antenna defined by an iteration identical to said first fractal antenna, (c) a second fractal antenna defined by an iteration identical to said first fractal antenna but having a different configuration, (d) a second fractal antenna defined by at least a third-order iteration, (e) a second fractal antenna defined by at least a third-order iteration and having a configuration similar to said first fractal antenna, (f) a second fractal antenna angularly rotated relative to said first fractal antenna, and (g) a second fractal antenna having a portion that defines a cut.

15. The tunable fractal antenna system of claim **13**, further including a feedline;

wherein said antenna system is tunable by varying at least one parameter selected from a group consisting of (a) said distance Δ, (b) relative rotation between said first fractal antenna and said conductive element, (c) location at which a center lead of said feedline is coupled to said first fractal antenna, (d) location of a cut in said first fractal antenna, and (e) size of a cut in said first fractal antenna.

16. The tunable fractal antenna system of claim **13**, wherein said distance Δ has at least one characteristic selected from a group consisting of (a) said first fractal antenna and said conductive element are spaced-apart in different planes by a distance $\Delta \leqq 0.05\lambda$ where λ is wavelength at a resonant frequency of said antenna system in free space, (b) said first fractal antenna and said conductive element are spaced-apart in a common plane by said distance Δ, and (c) at least one of said first fractal antenna and said conductive element is non-planar and said distance Δ defines a closest distance separating said first fractal antenna from said conductive element.

17. A method of tuning a fractal resonator system, comprising:

disposing a first fractal member a distance Δ from a conductive element;

said first fractal member including a first element having a portion that includes at least a first motif selected from a family consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia; and a first replication of said first motif and a second replication of said first motif such that a point chosen on a geometric figure represented by said first motif will result in a corresponding point on said first replication and on said second replication of said first motif; wherein there exists at least one non-straight line locus connecting each said point;

wherein a replication of said first motif is a change selected from a group consisting of (a) a rotation and change of scale of said first motif, (b) a linear displacement translation and a change of scale of said first motif, and (c) a rotation and a linear displacement translation and a change of scale of said first motif; and

tuning said fractal resonator system by modifying at least one parameter selected from a group consisting of (a) a magnitude of said distance Δ, (b) an angular orientation between said first fractal member and said conductive element, (c) extent of curvature associated with at least one of said first fractal member and said conductive element, (d) size of at least one of said first fractal member and said conductive element, (e) shape of at least one of said first fractal member and said conductive element, (f) location of said conductive element relative to said first fractal member, (g) existence of a cut defined in at least one of said first fractal member and said conductive element, and (g) location of feedline coupling to at least one of said first fractal member and said conductive element.

18. The method of claim **17**, wherein said system is an antenna system.

[57] **ABSTRACT**

A microstrip patch antenna having reduced size is implementing by providing a substrate having on one surface a conductive fractal pattern, and having on the other surface a conductive pattern that may (but need not) also be a fractal pattern. The fractal pattern is of order N≧1, and if fractal patterns are formed on each substrate surface, the fractal family and fractal iteration number may be different. So fractalizing at least one conductive surface permits reduction of substrate dimension may be reduced to one-eighth wavelength.

MICROSTRIP PATCH ANTENNA WITH FRACTAL STRUCTURE

RELATION TO PREVIOUSLY FILED PATENT APPLICATIONS

This application claims priority from applicant's U.S. provisional patent application No. 60/030,633 filed Nov. 8, 1996 entitled "MICROSTRIP PATCH ANTENNAE INCORPORATING 1 AND/OR 2 SIDES OF FRACTAL STRUCTURE ELEMENTS".

Applicant also refers to and incorporates herein by reference applicant's U.S. application Ser. No. 08/649,825 filed May 17, 1996 entitled "FRACTAL ANTENNA GROUND COUNTERPOISE, GROUND PLANES, AND LOADING ELEMENTS", now abandoned, applicant's patent application Ser. No. 08,609,514 filed Mar. 1, 1996 entitled "TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS", now abandoned, and applicant's patent application Ser. No. 08/512,954 filed Aug. 9, 1995 entitled "FRACTAL ANTENNAS AND FRACTAL RESONATORS", now abandoned.

FIELD OF THE INVENTION

The present invention relates to microstrip patch antennas and more specifically to providing such antennas with fractal structure elements.

BACKGROUND OF THE INVENTION

Antenna are used to radiate and/or receive typically electromagnetic signals, preferably with antenna gain, directivity, and efficiency. Practical antenna design traditionally involves trade-offs between various parameters, including antenna gain, size, efficiency, and bandwidth.

Antenna design has historically been dominated by Euclidean geometry. In such designs, the closed antenna area is directly proportional to the antenna perimeter. For example, if one doubles the length of an Euclidean square (or "quad") antenna, the enclosed area of the antenna quadruples. Classical antenna design has dealt with planes, circles, triangles, squares, ellipses, rectangles, hemispheres, paraboloids, and the like, (as well as lines).

With respect to antennas, prior art design philosophy has been to pick a Euclidean geometric construction, e.g., a quad, and to explore its radiation characteristics, especially with emphasis on frequency resonance and power patterns. The unfortunate result is that antenna design has far too long concentrated on the ease of antenna construction, rather than on the underlying electromagnetics.

Many prior art antennas are based upon closed-loop or island shapes. Experience has long demonstrated that small sized antennas, including loops, do not work well, one reason being that radiation resistance ("R") decreases sharply when the antenna size is shortened. A small sized loop, or even a short dipole, will exhibit a radiation pattern of ½λ and ¼λ, respectively, if the radiation resistance R is not swamped by substantially larger ohmic ("O") losses. Ohmic losses can be minimized using impedance matching networks, which can be expensive and difficult to use. But although even impedance matched small loop antennas can exhibit 50% to 85% efficiencies, their bandwidth is inherently narrow, with very high Q, e.g., Q>50. As used herein, Q is defined as (transmitted or received frequency)/(3 dB bandwidth).

Applicant's above-referenced co-pending patent applications depict examples of fractal geometry, which geometry may be grouped into random fractals, which are also termed chaotic or Brownian fractals and include a random noise components, or deterministic fractals.

In deterministic fractal geometry, a self-similar structure results from the repetition of a design or motif (or "generator"), on a series of different size scales. One well known treatise in this field is *Fractals, Endlessly Repeated Geometrical Figures*, by Hans Lauwerier, Princeton University Press (1991), which treatise applicant refers to and incorporates herein by reference. Lauwerier notes that in its replication, the motif may be rotated, translated, scaled in dimension, or a combination of any of these characteristics. Thus, as used herein, second order of iteration or N=2 means the fundamental motif has been replicated, after rotation, translation, scaling (or a combination of each) into the first order iteration pattern. A higher order, e.g., N=3, iteration means a third fractal pattern has been generated by including yet another rotation, translation, and/or scaling of the first order motif.

Unintentionally, first order fractals have been used to distort the shape of dipole and vertical antennas to increase gain, the shapes being defined as a Brownian-type of chaotic fractals. See F. Landstorfer and R. Sacher, *Optimisation of Wire Antennas*, J. Wiley, New York (1985).

So-called microstrip patch antennas have traditionally been fabricated as two spaced-apart metal surfaces separated by a small width dielectric. The sides are dimensioned typically one-quarter wavelength or one-half wavelength at the frequency of interest. One surface is typically a simple euclidean structure such as a circle, a square, while the other side is a ground plane.

Attempting to reduce the physical size of such an antenna for a given frequency typically results in a poor feedpoint match (e.g., to coaxial or other feed cable), poor radiation bandwidth, among other difficulties.

Prior art antenna design does not attempt to exploit multiple scale self-similarity of real fractals. This is hardly surprising in view of the accepted conventional wisdom that because such antennas would be anti-resonators, and/or if suitably shrunken would exhibit so small a radiation resistance R, that the substantially higher ohmic losses O would result in too low an antenna efficiency for any practical use. Further, it is probably not possible to mathematically predict such an antenna design, and high order iteration fractal antennas would be increasingly difficult to fabricate and erect, in practice.

Thus, the use of fractals, especially higher order fractals, in fabricating microstrip patch antennas has not been investigated in the prior art.

Applicant's above-noted FRACTAL ANTENNA AND FRACTAL RESONATORS patent application provided a design methodology to produce smaller-scale antennas that exhibit at least as much gain, directivity, and efficiency as larger Euclidean counterparts. Such design approach should exploit the multiple scale self-similarity of real fractals, including N≧2 iteration order fractals. Further, said application disclosed a non-Euclidean resonator whose presence in a resonating configuration can create frequencies of resonance beyond those normally presented in series and/or parallel LC configurations. Applicant's above-noted TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS patent application provided devices and methods for tuning and/or adjusting such antennas and resonators. Said application further disclosed the use of non-Euclidean resonators whose presence in a resonating configuration could create frequencies of resonance beyond those normally presented in series and/or parallel LC configurations.

However, such antenna design approaches and tuning approaches should also be useable with microstrip patch antennas and elements for such antennas. Thus, there is a need for a method by which microstrip patch antennas could be made smaller without sacrificing antenna bandwidth, while preserving good feedpoint impedance matching, and while maintaining acceptable gain and frequency characteristics.

The present invention provides such microstrip patch antennas, and elements for such antennas.

SUMMARY OF THE INVENTION

The present invention provides a microstrip patch antenna comprising spaced-apart first and second conductive surfaces separated by a dielectric material. The dielectric material thickness preferably is substantially less than one wavelength for the frequency of interest.

At least one of the surfaces is fabricated to define a fractal pattern of first or higher iteration order. Overall dimensions of the surfaces may be reduced below the one-quarter to one-half wavelength commonly found in the prior art.

Radio frequency feedline coupling to the microstrip patch antenna may be made at a location on the antenna pattern structure, or through a conductive feedtab strip that may be fabricated along with the conductive pattern on one or both surfaces of the antenna. The resultant antenna may be sized smaller than a non-fractal counterpart (e.g., approximately one-eighth wavelength provides good performance at about 900 MHz.) while preserving good, preferably 50Ω, feedpoint impedance. Further bandwidth can actually be increased, and resonant frequency lowered.

Other features and advantages of the invention will appear from the following description in which the preferred embodiments have been set forth in detail, in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a sideview of a microstrip patch antenna with at least one fractal element, according to the present invention;

FIG. **2** is a top plan view of an exemplary fractal element (a Sierpinski square gasket, including an optional feedtab, according to the present invention;

FIG. **3** is a top plan view of an exemplary alternative fractal element (a diffusion limited aggregate), including an optional feed pad, according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

In overview, the present invention provides a microstrip patch antenna with at least one element whose shape, at least is part, is substantially a fractal of iteration order $N \geqq 1$. The resultant antenna is smaller than its Euclidean counterpart, provides close to 50Ω termination impedance, exhibits acceptable gain, increased bandwidth, and decreased resonant frequency than its Euclidean counterpart.

In contrast to Euclidean geometric antenna design, a fractal antenna ground counterpoise according to the present invention has a perimeter that is not directly proportional to area. For a given perimeter dimension, the enclosed area of a multi-iteration fractal area will always be at least as small as any Euclidean area.

Using fractal geometry, the ground element has a self-similar structure resulting from the repetition of a design or motif (or "generator"), which motif is replicated using rotation, translation, and/or scaling (or any combination thereof). The fractal portion of the element has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, yb_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates of a preceding iteration, and where f(x,y) and g(x,y) are functions defining the fractal motif and behavior.

For example, fractals of the Julia set may be represented by the form:

$$x_{N+1}=x_N^2-y_N^2+a$$

$$y_{N+1}=2x_N \cdot y_N=b$$

In complex notation, the above may be represented as:

$$Z_{N+1}=Z_N^2+C$$

Although it is apparent that fractals can comprise a wide variety of forms for functions f(x,y) and g(x,y), it is the iterative nature and the direct relation between structure or morphology on different size scales that uniquely distinguish f(x,y) and g(x,y) from non-fractal forms. Many references including the Lauwerier treatise set forth equations appropriate for f(x,y) and g(x,y).

Iteration (N) is defined as the application of a fractal motif over one size scale. Thus, the repetition of a single size scale of a motif is not a fractal as that term is used herein. Multi-fractals may of course be implemented, in which a motif is changed for different iterations, but eventually at least one motif is repeated in another iteration.

Referring now to FIG. **1**, a microstrip patch antenna **10** according to the present invention is shown coupled by coaxial or other cable (or equivalent) **20** to a source of radio frequency **30**. Antenna **10** comprises a substrate **40** whose top-to-bottom thickness is preferably substantially less than one wavelength at the frequency of interest, e.g., the radio frequency or band of radio frequencies coupled by cable **20** to antenna **10**. Preferably the effective dimension of substrate is one-eighth wavelength at such frequency.

On its first surface, substrate **40** is initially covered by a conductive layer of material **50** that is etched away or otherwise removed in areas other than the desired fractal pattern **(60)** design, to expose the substrate. The remaining conductive trace portion defines a fractal element, according to the present invention.

Similarly on its second surface, substrate **40** is initially covered by a conductive layer of material **70** that is selectively removed so as to leave a desired pattern **(80)** that may also be a fractal pattern, according to the present invention. Alternatively, conductive material defining the desired patterns **60**, **80** could be deposited upon substrate **40**, rather than beginning fabrication with a substrate clad or otherwise having conductive surfaces, portions of which are removed.

Preferably feedtabs **90** and **100** are coupled, respectively, to edge regions of the first and second surfaces of substrate **40** to facilitate electrical radio frequency coupling between cable **20** and patterns **60** and/or **80**. These feedtabs preferably are etched using the same conductive material originally found on the upper or lower surfaces of substrate **40**, or may otherwise be formed using techniques known to those skilled in the relevant art. If patterns **60** and **80** are deposited rather than etched, then feedtabs **90**, **100** may be deposited at the same fabrication step.

Substrate **40** is a non-conductive material, and by way of example may be a silicon wafer, a rigid or a flexible plastic-like material, perhaps Mylar™ material, or the non-conductive portion of a printed circuit board, paper, epoxy, among other materials. The original conductive material on the first and/or second surfaces may be deposited doped polysilicon for a semiconductor substrate **40**, or copper (or other conductor) for a printed circuit board substrate.

FIG. **2** is a plan view of one surface of antenna **10** (it matters not which), and depicts a first iteration fractal conductive pattern, although a fractal pattern with higher than first iteration could instead be used. The pattern shown in FIG. **2** is often referred to as a Siepinski (square) gasket pattern. A margin is shown in FIG. **2** between the outer perimeter of the pattern and the edge of the substrate; however no such margin is required. Although FIG. **2** shows inclusion of feedtab **90** or **100**, radio frequency feed may be made elsewhere on the surface, for example at any point **110**.

If the fractal pattern of FIG. **2** represents one surface of antenna **10**, the opposite surface need not define a fractal pattern, but may in fact do so. For example, one surface may define a fractal pattern and the opposite surface may be entirely conductive, or may define on the substrate a conductive circle, etc. If the pattern on the opposite surface is also a fractal, there is no requirement that it be the same iteration fractal as is defined on the first surface, or that it be the same fractal type. While common fractal families include Koch, Minkowski, Julia, diffusion limited aggregates, fractal trees, Mandelbrot, microstrip patch antennas with fractal element(s) according to the present invention may be implemented with other fractals as well.

FIG. **3** depicts a pattern **60** or **80** in which a different fractal pattern is defined, a so-called diffusion limited aggregate pattern. It is understood, however, that according to the present invention, a great variety of fractal patterns of first or higher iteration may be defined on the first and/or second surface of antenna **10**. In FIG. **3**, while a feedtab **90** or **100** is shown, it is again understood that radio frequency feed may be made essentially anywhere on the fractal pattern, e.g., at a point **110**.

In one embodiment, applicant fabricated an antenna **10** having sides dimensioned to about one-eighth wavelength for a frequency of about 900 MHz. Those skilled in the art will readily appreciate that a microstrip patch antenna dimensioned to one-eighth wavelength is substantially smaller than prior art non-fractal microstrip patch antennas, in which dimensions are one-quarter or one-half wavelength in size. At 900 MHz, bandwidth was about 5% to about 8% of nominal frequency. Gain and matching impedance were acceptable, and indeed substantially 50Ω impedance is realized without the need for impedance transforming devices.

Modifications and variations may be made to the disclosed embodiments without departing from the subject and spirit of the invention as defined by the following claims. It will be appreciated, for example, that the present invention may be implemented and adjusted and used in ways described in any of applicant's referenced co-pending applications.

What is claimed is:

1. A microstrip patch antenna including:

a substrate having spaced-apart first and second surfaces, said substrate having a thickness substantially smaller than a wavelength at a frequency to be coupled to said antenna;

a conductive pattern defining a fractal of iteration order N disposed on the first surface, wherein said fractal is defined as a superposition over at least N=1 interations of a motiff, an iteration being placement of said motif upon a base figure through at least one positioning selected from a group consisting of (i) rotation, (ii) stretching, and (iii) translation;

wherein said motif is selected from a group consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia; and

a conductive pattern disposed on the second surface.

2. The antenna of claim **1**, wherein said pattern on said second surface defines a fractal.

3. The antenna of claim **1**, wherein said motif has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, y_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates for iteration N, and where f(x,y) and g(x,y) are functions defining said motif.

4. The antenna of claim **1**, wherein said antenna has a perimeter compression parameter (PC) defined by:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC = A \cdot \log [N(D+C)]$$

in which A and C are constant coefficients for a given said motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization, respectively.

5. The antenna of claim **1**, in which said antenna is fabricated in a manner selected from the group consisting of (i) forming upon an insulator substrate a conductive layer defining said fractal, (ii) forming upon a flexible insulator substrate a conductive layer defining said fractal; (iii) forming upon a semiconductor substrate a layer of conductive material to define said fractal, and (iv) removing from a substrate having a surface covered with conductive material a portion of said conductive material to form said fractal.

6. The antenna of claim **1**, wherein said substrate is sized to less than one-quarter wavelength at a frequency of radio frequency signals to be coupled to said antenna.

7. The antenna of claim **1**, wherein said substrate is sized to approximately one-eighth wavelength at a frequency of radio frequency signals to be coupled to said antenna.

8. The antenna of claim **7**, wherein said frequency is approximately 900 MHz.

9. A microstrip patch antenna including:

a substrate having spaced-apart first and second surfaces, said substrate having a thickness substantially smaller than a wavelength at a frequency to be coupled to said antenna;

a conductive pattern defining a fractal of iteration order N disposed on the first surface, where said fractal is defined as a superposition over at least N=1 interations of a motiff, an iteration being placement of said motif upon a base figure through at least one positioning selected from a group consisting of (i) rotation, (ii) stretching, and (iii) translation;

wherein said antenna has a perimeter compression parameter (PC) defined by:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC = A \cdot \log [N(D+C)]$$

in which A and C are constant coefficients for a given said motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization respectively; and

a conductive pattern disposed on the second surface.

10. The antenna of claim **9**, wherein said motif is selected from a family consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

11. A method of fabricating a microstrip patch antenna, the method including the following steps:

(a) providing a substrate having spaced-apart first and second surfaces and having a substrate thickness substantially smaller than a wavelength at a frequency to be coupled to said antenna;

(b) disposing on the first surface of said substrate a conductive pattern defining a fractal of iteration order N formed; and

(c) disposing on the second surface of said substrate a conductive pattern;

wherein said motif is selected from a family consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

12. The method of claim **11**, wherein at step (c) said conductive pattern is formed so as to define a fractal.

13. The method of claim **11**, wherein at step (b), said fractal on said first surface is defined as a superposition over at least N=1 iterations of a motif, an iteration being placement of said motif upon a base figure through at least one positioning selected from the group consisting of (i) rotation, (ii) stretching, and (iii) translation.

14. The method of claim **11**, wherein said motif has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, y_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates for iteration N, and where f(x,y) and g(x,y) are functions defining said motif.

15. The antenna of claim **9**, wherein said antenna is fabricated in a manner selected from the group consisting of (i) forming upon an insulator substrate a conductive layer defining said fractal, (ii) forming upon a flexible insulator substrate a conductive layer defining said fractal; (iii) forming upon a semiconductor substrate a layer of conductive material to define said fractal, and (iv) removing from a substrate having a surface covered with conductive material a portion of said conductive material to form said fractal.

16. The method of claim **11**, wherein said antenna has a perimeter compression parameter (PC) defined by:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC=A\cdot\log\,[N(D+C)]$$

in which A and C are constant coefficients for a given said motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization, respectively.

17. The method of claim **11**, in which said antenna is fabricated in a manner selected from the group consisting of (i) forming upon an insulator substrate a conductive layer defining said fractal, (ii) forming upon a flexible insulator substrate a conductive layer defining said fractal; (iii) forming upon a semiconductor substrate a layer of conductive material to define said fractal, and (iv) providing a substrate having a surface covered with conductive material, and removing a portion of said conductive material to form said fractal.

18. The method of claim **11**, wherein said substrate is sized to less than one-quarter wavelength at a frequency of radio frequency signals to be coupled to said antenna.

19. The method of claim **11**, wherein at step (a) said substrate is sized to approximately one-eighth wavelength at a frequency of radio frequency signals to be coupled to said antenna.

20. The method of claim **19**, wherein said frequency is approximately 900 MHz.

21. A method of fabricating a microstrip patch antenna, the method including the following steps:

(a) providing a substrate having spaced-apart first and second surfaces and having a substrate thickness substantially smaller than a wavelength at a frequency to be coupled to said antenna;

(b) disposing on the first surface of said substrate a conductive pattern defining a fractal of iteration order N formed; and

(c) disposing on the second surface of said substrate a conductive pattern;

wherein said antenna has a perimeter compression parameter (PC) defined by:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC=A\cdot\log\,[N(D+C)]$$

in which A and C are constant coefficients for a given said motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization, respectively.

22. The method of claim **21**, wherein at step (c) said conductive pattern is formed so as to define a fractal.

23. The method of claim **21**, wherein said antenna is fabricated in a manner selected from the group consisting of (i) forming upon an insulator substrate a conductive layer defining said fractal, (ii) forming upon a flexible insulator substrate a conductive layer defining said fractal; (iii) forming upon a semiconductor substrate a layer of conductive material to define said fractal, and (iv) providing a substrate having a surface covered with conductive material, and removing a portion of said conductive material to form said fractal.

24. The method of claim **21**, wherein said substrate is sized to less than one-quarter wavelength at a frequency of radio frequency signals to be coupled to said antenna.

25. The method of claim **21**, wherein at step (a) said substrate is sized to approximately one-eighth wavelength at a frequency of radio frequency signals to be coupled to said antenna.

26. The method of claim **25**, wherein said frequency is approximately 900 MHz.

[57] **ABSTRACT**

An antenna system includes a ground counterpoise or a top-hat located load assembly having at least one element whose physical shape is at least partially defined as a first or higher iteration deterministic fractal. The resultant ground counterpoise may rely upon an opening angle for performance, and produces a more compact antenna system relative to prior art non-Euclidean ground counterpoise elements. A vertical antenna system may be fabricated with fractal ground elements and a vertical element that may also be a fractal. Gain characteristics of antenna systems utilizing a fractal ground counterpoise are no worse than prior art, larger, systems, and exhibit improved vertical polarization characteristics, and a termination impedance of about 30Ω. A vertical antenna system preferably includes vertically spaced-apart fractal conductive and passive elements, and one or more fractal ground elements. The resultant antenna system may be tuned by rotating the vertical elements relative to each other, and/or by varying the spaced-apart distance therebetween. Fractalized ground counterpoise elements may be fabricated on a flexible printed circuit substrate, and/or placed within the support mount of a cellular telephone car antenna. A vertical antenna having a fractalized top-hat loading assembly advantageously reduces resonant frequency, size and area of the loading assembly, without substantial penalty in performance.

FRACTAL ANTENNA GROUND COUNTERPOISE, GROUND PLANES, AND LOADING ELEMENTS

RELATION TO PREVIOUSLY FILED PATENT APPLICATIONS

This is a continuation of application Ser. No. 08/649,825 filed May 17, 1996 is now abandoned.

This application is a continuing application from applicant's pending patent application Ser. No. 08,609,514 entitled TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS, filed on Mar. 1, 1996, abandoned, which itself is a continuation-in-part of applicant's pending patent application Ser. No. 08/512,954 entitled FRACTAL ANTENNAS AND FRACTAL RESONATORS, filed on Aug. 9, 1995, now abandoned.

FIELD OF THE INVENTION

The present invention relates to antennas and resonators, and specifically to designing and tuning non-Euclidian antenna ground radials, ground counterpoise or planes, top-loading elements, and antennas using such elements.

BACKGROUND OF THE INVENTION

Antenna are used to radiate and/or receive typically electromagnetic signals, preferably with antenna gain, directivity, and efficiency. Practical antenna design traditionally involves trade-offs between various parameters, including antenna gain, size, efficiency, and bandwidth.

Antenna design has historically been dominated by Euclidean geometry. In such designs, the closed antenna area is directly proportional to the antenna perimeter. For example, if one doubles the length of an Euclidean square (or "quad") antenna, the enclosed area of the antenna quadruples. Classical antenna design has dealt with planes, circles, triangles, squares, ellipses, ectangles, hemispheres, paraboloids, and the like, (as ell as lines). Similarly, resonators, typically apacitors ("C") coupled in series and/or parallel with inductors ("L"), traditionally are implemented with Euclidian inductors.

With respect to antennas, prior art design philosophy has been to pick a Euclidean geometric construction, e.g., a quad, and to explore its radiation characteristics, especially with emphasis on frequency resonance and power patterns. The unfortunate result is that antenna design has far too long concentrated on the ease of antenna construction, rather than on the underlying electromagnetics.

Many prior art antennas are based upon closed-loop or island shapes. Experience has long demonstrated that small sized antennas, including loops, do not work well, one reason being that radiation resistance ("R") decreases sharply when the antenna size is shortened. A small sized loop, or even a short dipole, will exhibit a radiation pattern of ½ λ and ¼ λ, respectively, if the radiation resistance R is not swamped by substantially larger ohmic ("O") losses. Ohmic losses can be minimized using impedance matching networks, which can be expensive and difficult to use. But although even impedance matched small loop antennas can exhibit 50% to 85% efficiencies, their bandwidth is inherently narrow, with very high Q, e.g., $Q>50$. As used herein, Q is defined as (transmitted or received frequency)/(3 dB bandwidth).

As noted, it is well known experimentally that radiation resistance R drops rapidly with small area Euclidean antennas. However, the theoretical basis is not generally known, and any present understanding (or misunderstanding) appears to stem from research by J. Kraus, noted in *Antennas* (Ed. 1), McGraw Hill, New York (1950), in which a circular loop antenna with uniform current was examined. Kraus' loop exhibited a gain with a surprising limit of 1.8 dB over an isotropic radiator as loop area fells below that of a loop having a 1 λ-squared aperture. For small loops of area $A<\lambda^2/100$, radiation resistance R was given by:

$$R = K\cdot\left(\frac{A}{\lambda^2}\right)^2$$

where K is a constant, A is the enclosed area of the loop, and λ is wavelength. Unfortunately, radiation resistance R can all too readily be less than 1 Ω for a small loop antenna.

From his circular loop research Kraus generalized that calculations could be defined by antenna area rather than antenna perimeter, and that his analysis should be correct for small loops of any geometric shape. Kraus' early research and conclusions that small-sized antennas will exhibit a relatively large ohmic resistance O and a relatively small radiation resistance R, such that resultant low efficiency defeats the use of the small antenna have been widely accepted. In fact, some researchers have actually proposed reducing ohmic resistance O to 0 Ω by constructing small antennas from superconducting material, to promote efficiency.

As noted, prior art antenna and resonator design has traditionally concentrated on geometry that is Euclidean. However, one non-Euclidian geometry is fractal geometry. Fractal geometry may be grouped into random fractals, which are also termed chaotic or Brownian fractals and include a random noise components, such as depicted in FIG. **3**, or deterministic fractals such as shown in FIG. **1**C.

In deterministic fractal geometry, a self-similar structure results from the repetition of a design or motif (or "generator"), on a series of different size scales. One well known treatise in this field is *Fractals, Endlessly Repeated Geometrical Figures*, by Hans Lauwerier, Princeton University Press (1991), which treatise applicant refers to and incorporates herein by reference.

FIGS. **1**A–**2**D depict the development of some elementary forms of fractals. In FIG. **1**A, a base element **10** is shown as a straight line, although a curve could instead be used. In FIG. **1**B, a so-called Koch fractal motif or generator **20-1**, here a triangle, is inserted into base element **10**, to form a first order iteration ("N") design, e.g., N=1. In FIG. **1**C, a second order N=2 iteration design results from replicating the triangle motif **20-1** into each segment of FIG. **1**B, but where the **20-1**' version has been differently scaled, here reduced in size. As noted in the Lauwerier treatise, in its replication, the motif may be rotated, translated, scaled in dimension, or a combination of any of these characteristics. Thus, as used herein, second order of iteration or N=2 means the fundamental motif has been replicated, after rotation, translation, scaling (or a combination of each) into the first order iteration pattern. A higher order, e.g., N=3, iteration means a third fractal pattern has been generated by including yet another rotation, translation, and/or scaling of the first order motif.

In FIG. **1**D, a portion of FIG. **1**C has been subjected to a further iteration (N=3) in which scaled-down versions **20-1**' of the triangle motif **20-1** have been inserted into each segment of the left half of FIG. **1**C. FIGS. **2**A–**2**C follow what has been described with respect to FIGS. **1**A–**1**C, except that a rectangular motif **20-2** has been adopted which motif is denoted **20-2**' in FIG. **2**C, and **20-2**" in FIG. **2**D.

FIG. 2D shows a pattern in which a portion of the left-hand side is an N=3 iteration of the **20-2** rectangle motif, and in which the center portion of the figure now includes another motif, here a **20-1** type triangle motif, and in which the right-hand side of the figure remains an N=2 iteration.

Traditionally, non-Euclidean designs including random fractals have been understood to exhibit antiresonance characteristics with mechanical vibrations. It is known in the art to attempt to use non-Euclidean random designs at lower frequency regimes to absorb, or at least not reflect sound due to the antiresonance characteristics. For example, M. Schroeder in *Fractals, Chaos, Power Laws* (1992), W. H. Freeman, New York discloses the use of presumably random or chaotic fractals in designing sound blocking diffusers for recording studios and auditoriums.

Experimentation with non-Euclidean structures has also been undertaken with respect to electromagnetic waves, including radio antennas. In one experiment, Y. Kim and D. Jaggard in *The Fractal Random Array*, Proc. IEEE 74, 1278–1280 (1986) spread-out antenna elements in a sparse microwave array, to minimize sidelobe energy without having to use an excessive number of elements. But Kim and Jaggard did not apply a fractal condition to the antenna elements, and test results were not necessarily better than any other techniques, including a totally random spreading of antenna elements. More significantly, the resultant array was not smaller than a conventional Euclidean design.

Prior art spiral antennas, cone antennas, and V-shaped antennas may be considered as a continuous, deterministic first order fractal, whose motif continuously expands as distance increases from a central point. A log-periodic antenna may be considered a type of continuous fractal in that it is fabricated from a radially expanding structure. However, log periodic antennas do not utilize he antenna perimeter for radiation, but instead rely upon an arc-like opening angle in the antenna geometry.

Such opening angle is an angle that defines the size-scale of the log-periodic structure, which structure is proportional to the distance from the antenna center multiplied by the opening angle. Further, known log-periodic antennas are not necessarily smaller than conventional driven element-parasitic element antenna designs of similar gain.

Unintentionally, first order fractals have been used to distort the shape of dipole and vertical antennas to increase gain, the shapes being defined as a Brownian-type of chaotic fractals. See F. Landstorfer and R. Sacher, *Optimisation of Wire Antennas*, J. Wiley, New York (1985). FIG. **3** depicts three bent-vertical antennas developed by Landstorfer and Sacher through trial and error, the plots showing the actual vertical antennas as a function of x-axis and y-axis coordinates that are a function of wavelength. The “EF” and “BF” nomenclature in FIG. **3** refer respectively to end-fire and back-fire radiation patterns of the resultant bent-vertical antennas.

First order fractals have also been used to reduce horn-type antenna geometry, in which a double-ridge horn configuration is used to decrease resonant frequency. See J. Kraus in *Antennas*, McGraw Hill, New York (1885). The use of rectangular, box-like, and triangular shapes as impedance-matching loading elements to shorten antenna element dimensions is also known in the art.

Whether intentional or not, such prior art attempts to use a quasi-fractal or fractal motif in an antenna employ at best a first order iteration fractal. By first iteration it is meant that one Euclidian structure is loaded with another Euclidean structure in a repetitive fashion, using the same size for repetition. FIG. 1C, for example, is not first order because the **20-1**' triangles have been shrunk with respect to the size of the first motif **20-1**.

Prior art antenna design does not attempt to exploit multiple scale self-similarity of real fractals. This is hardly surprising in view of the accepted conventional wisdom that because such antennas would be anti-resonators, and/or if suitably shrunken would exhibit so small a radiation resistance R, that the substantially higher ohmic losses O would result in too low an antenna efficiency for any practical use. Further, it is probably not possible to mathematically predict such an antenna design, and high order iteration fractal antennas would be increasingly difficult to fabricate and erect, in practice.

FIGS. **4**A and **4**B depict respective prior art series and parallel type resonator configurations, comprising capacitors C and Euclidean inductors L. In the series configuration of FIG. **4**A, a notch-filter characteristic is presented in that the impedance from port A to port B is high except at frequencies approaching resonance, determined by $1/\surd(LC)$.

In the distributed parallel configuration of FIG. **4**B, a low-pass filter characteristic is created in that at frequencies below resonance, there is a relatively low impedance path from port A to port B, but at frequencies greater than resonant frequency, signals at port A are shunted to ground (e.g., common terminals of capacitors C), and a high impedance path is presented between port A and port B. Of course, a single parallel LC configuration may also be created by removing (e.g., short-circuiting) the rightmost inductor L and right two capacitors C, in which case port B would be located at the bottom end of the leftmost capacitor C.

In FIGS. **4**A and **4**B, inductors L are Euclidean in that increasing the effective area captured by the inductors increases with increasing geometry of the inductors, e.g., more or larger inductive windings or, if not cylindrical, traces comprising inductance. In such prior art configurations as FIGS. **4**A and **4**B, the presence of Euclidean inductors L ensures a predictable relationship between L, C and frequencies of resonance.

Applicant’s above-noted FRACTAL ANTENNA AND FRACTAL RESONATORS patent application provided a design methodology to produce smaller-scale antennas that exhibit at least as much gain, directivity, and efficiency as larger Euclidean counterparts. Such design approach should exploit the multiple scale self-similarity of real fractals, including $N \geqq 2$ iteration order fractals. Further, said application disclosed a non-Euclidean resonator whose presence in a resonating configuration can create frequencies of resonance beyond those normally presented in series and/or parallel LC configurations. Applicant’s above-noted TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS patent application provided devices and methods for tuning and/or adjusting such antennas and resonators. Said application further disclosed the use of non-Euclidean resonators whose presence in a resonating configuration could create frequencies of resonance beyond those normally presented in series and/or parallel LC configurations.

However, such antenna design approaches and tuning approaches should also be useable with vertical antennas, permitting the downscaling of one or more radial ground plane elements, and/or ground planes, and/or ground counterpoises, and/or top-hat loading elements.

The present invention provides such antennas, radial ground plane elements, ground planes, ground counterpoises, and top-hat loading elements, as well as methods for their design.

SUMMARY OF THE INVENTION

The present invention provides an antenna with a ground plane or ground counterpoise system that has at least one element whose shape, at least is part, is substantially a deterministic fractal of iteration order $N \geqq 1$. (The term "ground counterpoise" will be understood to include a ground plane, and/or at least one ground element.) Using fractal geometry, the antenna ground counterpoise has a self-similar structure resulting from the repetition of a design or motif (or "generator") that is replicated using rotation, and/or translation, and/or scaling. The fractal element will have x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, yb_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N define coordinates for a preceding iteration, and where f(x,y) and g(x,y) are functions defining the fractal motif and behavior. In another aspect, a vertical antenna is top-loaded with a so-called top-hat assembly that includes at least one fractal element. A fractalized top-hat assembly advantageously reduces resonant frequency, as well as the physical size and area required for the top-hat assembly.

In contrast to Euclidean geometric antenna design, deterministic fractal elements according to the present invention have a perimeter that is not directly proportional to area. For a given perimeter dimension, the enclosed area of a multi-iteration fractal will always be as small or smaller than the area of a corresponding conventional Euclidean element.

A fractal antenna has a fractal ratio limit dimension D given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization, respectively.

As used herein, a fractal antenna perimeter compression parameter (PC) is defined as:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC = A \cdot \log[N(D+C)]$$

in which A and C are constant coefficients for a given fractal motif, N is an iteration number, and D is the fractal dimension, defined above.

Radiation resistance (R) of a fractal antenna decreases as a small power of the perimeter compression (PC), with a fractal loop or island always exhibiting a substantially higher radiation resistance than a small Euclidean loop antenna of equal size. In the present invention, deterministic fractals are used wherein A and C have large values, and thus provide the greatest and most rapid element-size shrinkage. A fractal antenna according to the present invention will exhibit an increased effective wavelength.

The number of resonant nodes of a fractal loop-shaped antenna increases as the iteration number N and is at least as large as the number of resonant nodes of an Euclidean island with the same area. Further, resonant frequencies of a fractal antenna include frequencies that are not harmonically related.

An antenna including a fractal ground counterpoise according to the present invention is smaller than its Euclidean counterpart but provides at least as much gain and frequencies of resonance and provides a reasonable termination impedance at its lowest resonant frequency. Such an antenna system can exhibit non-harmonically frequencies of resonance, a low Q and resultant good bandwidth, acceptable standing wave ratio ("SWR"), and a radiation impedance that is frequency dependent, and high efficiencies.

With respect to vertical antennas, the present invention enables such antennas to be realized with a smaller vertical element, and/or with smaller ground counterpoise, e.g., ground plane radial elements, and/or ground plane. The ground counterpoise element(s) are fractalized with $N \geqq 1$. In a preferred embodiment, the vertical element is also a fractal system, preferably comprising first and second spaced-apart fractal elements.

A fractal antenna system having a fractal ground counterpoise and a fractal vertical preferably is tuned according to applicant's above-referenced TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS, by placing an active (or driven) fractal antenna or resonator a distance Δ from a second conductor. Such disposition of the antenna and second conductor advantageously lowers resonant frequencies and widens bandwidth for the fractal antenna. In some embodiments, the fractal antenna and second conductor are non-coplanar and λ is the separation distance therebetween, preferably $\leqq 0.05\ \lambda$ for the frequency of interest ($1/\lambda$). In other embodiments, the fractal antenna and second conductive element may be planar, in which case λ a separation distance, measured on the common plane. In another embodiment, an antenna is loaded with a fractal "top-hat" assembly, which can provide substantial reduction in antenna size.

The second conductor may in fact be a second fractal antenna of like or unlike configuration as the active antenna. Varying the distance Δ tunes the active antenna and thus the overall system. Further, if the second element, preferably a fractal antenna, is angularly rotated relative to the active antenna, resonant frequencies of the active antenna may be varied.

Providing a cut in the fractal antenna results in new and different resonant nodes, including resonant nodes having perimeter compression parameters, defined below, ranging from about three to ten. If desired, a portion of a fractal antenna may be cutaway and removed so as to tune the antenna by increasing resonance(s).

Tunable antenna systems with a fractal ground counterpoise need not be planar, according to the present invention. Fabricating the antenna system around a form such as a torroid ring, or forming the fractal antenna on a flexible substrate that is curved about itself results in field self-proximity that produces resonant frequency shifts. A fractal antenna and a conductive element may each be formed as a curved surface or even as a torroid-shape, and placed in sufficiently close proximity to each other to provide a useful tuning and system characteristic altering mechanism.

In the various embodiments, more than two elements may be used, and tuning may be accomplished by varying one or more of the parameters associated with one or more elements.

Other features and advantages of the invention will appear from the following description in which the preferred embodiments have been set forth in detail, in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1**A depicts a base element for an antenna or an inductor, according to the prior art;

FIG. **1**B depicts a triangular-shaped Koch fractal motif, according to the prior art;

FIG. **1**C depicts a second-iteration fractal using the motif of FIG. **1**B, according to the prior art;

FIG. **1**D depicts a third-iteration fractal using the motif of FIG. **1**B, according to the prior art;

FIG. **2**A depicts a base element for an antenna or an inductor, according to the prior art;

FIG. 2B depicts a rectangular-shaped Minkowski fractal motif, according to the prior art;

FIG. 2C depicts a second-iteration fractal using the motif of FIG. 2B, according to the prior art;

FIG. 2D depicts a fractal configuration including a third-order using the motif of FIG. 2B, as well as the motif of FIG. 1B, according to the prior art;

FIG. 3 depicts bent-vertical chaotic fractal antennas, according to the prior art;

FIG. 4A depicts a series L-C resonator, according to the prior art;

FIG. 4B depicts a distributed parallel L-C resonator, according to the prior art;

FIG. 5A depicts an Euclidean quad antenna system, according to the prior art;

FIG. 5B depicts a second-order Minkowski island fractal quad antenna, according to the present invention;

FIG. 6 depicts an ELNEC-generated free-space radiation pattern for an MI-2 fractal antenna, according to the present invention;

FIG. 7A depicts a Cantor-comb fractal dipole antenna, according to the present invention;

FIG. 7B depicts a torn square fractal quad antenna, according to the present invention;

FIG. 7C-1 depicts a second iteration Minkowski (MI-2) printed circuit fractal antenna, according to the present invention;

FIG. 7C-2 depicts a second iteration Minkowski (MI-2) slot fractal antenna, according to the present invention;

FIG. 7D depicts a deterministic dendrite fractal vertical antenna, according to the present invention; FIG. 7D-1A depicts a 0.25 λ vertical antenna with three 0.25 λ radial ground elements, according to the prior art;

FIG. 7D-1B depicts the gain pattern for the antenna of FIG. 7D-1A;

FIG. 7D-2A depicts a 0.25 λ vertical antenna with three fractal radial ground elements according to the present invention;

FIG. 7D-2B depicts the gain pattern for the antenna of FIG. 7D-2A;

FIG. 7D-3A depicts a “top-hat” loaded antenna, according to the prior art;

FIG. 7D-3B depicts the gain pattern for the antenna of FIG. 7D-3A;

FIG. 7D-4A depicts a ternary fractal “top-hat” loaded antenna, according the present invention;

FIG. 7D-4B depicts the gain pattern for the antenna of FIG. 7D-4A;

FIG. 7D-5 depicts an antenna having a fractal vertical element and fractal radial ground elements, according to the present invention;

FIG. 7E depicts a third iteration Minkowski island (MI-3) fractal quad antenna, according to the present invention;

FIG. 7F depicts a second iteration Koch fractal dipole, according to the present invention;

FIG. 7G depicts a third iteration dipole, according to the present invention;

FIG. 7H depicts a second iteration Minkowski fractal dipole, according to the present invention;

FIG. 7I depicts a third iteration multi-fractal dipole, according to the present invention;

FIG. 8A depicts a generic system in which a passive or active electronic system communicates using a fractal antenna, according to the present invention;

FIG. 8B depicts a communication system in which several fractal antennas including a vertical antenna with a fractal ground counterpoise are electronically selected for best performance, according to the present invention;

FIG. 8C depicts a communication system in which electronically steerable arrays of fractal antennas are electronically selected for best performance, according to the present invention;

FIG. 9A depicts fractal antenna gain as a function of iteration order N, according to the present invention;

FIG. 9B depicts perimeter compression PC as a function of iteration order N for fractal antennas, according to the present invention;

FIG. 10A depicts a fractal inductor for use in a fractal resonator, according to the present invention;

FIG. 10B depicts a credit card sized security device utilizing a fractal resonator, according to the present invention;

FIG. 11A depicts an embodiment in which a fractal antenna is spaced-apart a distance Δ from a conductor element to vary resonant properties and radiation characteristics of the antenna, according to the present invention;

FIG. 11B depicts an embodiment in which a fractal antenna is coplanar with a ground plane and is spaced-apart a distance Δ' from a coplanar passive parasitic element to vary resonant properties and radiation characteristics of the antenna, according to the present invention;

FIG. 12A depicts spacing-apart first and second fractal antennas a distance Δ to decrease resonance and create additional resonant frequencies for the active or driven antenna, according to the present invention;

FIG. 12B depicts relative angular rotation between spaced-apart first and second fractal antennas Δ to vary resonant frequencies of the active or driven antenna, according to the present invention;

FIG. 13A depicts cutting a fractal antenna or resonator to create different resonant nodes and to alter perimeter compression, according to the present invention;

FIG. 13B depicts forming a non-planar fractal antenna or resonator on a flexible substrate that is curved to shift resonant frequency, apparently due to self-proximity electromagnetic fields, according to the present invention;

FIG. 13C depicts forming a fractal antenna or resonator on a curved torroidal form to shift resonant frequency, apparently due to self-proximity electromagnetic fields, according to the present invention;

FIG. 14A depicts forming a fractal antenna or resonator in which the conductive element is not attached to the system coaxial or other feedline, according to the present invention;

FIG. 14B depicts a system similar to FIG. 14A, but demonstrates that the driven fractal antenna may be coupled to the system coaxial or other feedline at any point along the antenna, according to the present invention;

FIG. 14C depicts an embodiment in which a supplemental ground plane is disposed adjacent a portion of the driven fractal antenna and conductive element, forming a sandwich-like system, according to the present invention;

FIG. 14D depicts an embodiment in which a fractal antenna system is tuned by cutting away a portion of the driven antenna, according to the present invention;

FIG. 15 depicts a communication system similar to that of FIG. 8A, in which several fractal antennas are tunable and are electronically selected for best performance, according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

In overview, the present invention provides an antenna system with a fractal ground counterpoise, e.g., a counterpoise and/or ground plane and/or ground element having at least one element whose shape, at least is part, is substantially a fractal of iteration order $N \geqq 1$. The resultant antenna is smaller than its Euclidean counterpart, provides close to 50 Ω termination impedance, exhibits at least as much gain and more frequencies of resonance than its Euclidean counterpart, including non-harmonically related frequencies of resonance, exhibits a low Q and resultant good bandwidth, acceptable SWR, a radiation impedance that is frequency dependent, and high efficiencies.

In contrast to Euclidean geometric antenna design, a fractal antenna ground counterpoise according to the present invention has a perimeter that is not directly proportional to area. For a given perimeter dimension, the enclosed area of a multi-iteration fractal area will always be at least as small as any Euclidean area. Using fractal geometry, the ground element has a self-similar structure resulting from the repetition of a design or motif (or "generator"), which motif is replicated using rotation, translation, and/or scaling (or any combination thereof). The fractal portion of the element has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, yb_N)$ and $Y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates of a preceding iteration, and where f(x,y) and g(x,y) are functions defining the fractal motif and behavior. For example, fractals of the Julia set may be represented by the form:

$$x_{N+1}=x_N^2-y_N^2+a$$

$$y_{N+1}=2x_N \cdot y_N=b$$

In complex notation, the above may be represented as:

$$z_{N+1}=z_N^2+c$$

Although it is apparent that fractals can comprise a wide variety of forms for functions f(x,y) and g(x,y), it is the iterative nature and the direct relation between structure or morphology on different size scales that uniquely distinguish f(x,y) and g(x,y) from non-fractal forms. Many references including the Lauwerier treatise set forth equations appropriate for f(x,y) and g(x,y).

Iteration (N) is defined as the application of a fractal motif over one size scale. Thus, the repetition of a single size scale of a motif is not a fractal as that term is used herein. Multi-fractals may of course be implemented, in which a motif is changed for different iterations, but eventually at least one motif is repeated in another iteration.

An overall appreciation of the present invention may be obtained by comparing FIGS. **5**A and **5**B. FIG. **5**A shows a conventional Euclidean quad antenna **5** having a driven element **10** whose four sides are each 0.25 λ long, for a total perimeter of 1 λ, where λ is the frequency of interest.

Euclidean element **10** has an impedance of perhaps 130 Ω, which impedance decreases if a parasitic quad element **20** is spaced apart on a boom **30** by a distance B of 0.1 λ to 0.25 λ. Parasitic element **20** is also-sized S=0.25 λ on a side, and its presence can improve directivity of the resultant two-element quad antenna. Element **10** is depicted in FIG. **5**A with heavier lines than element **20**, solely to avoid confusion in understanding the figure. Non-conductive spreaders **40** are used to help hold element **10** together and element **20** together.

Because of the relatively large drive impedance, driven element **10** is coupled to an impedance matching network or device **60**, whose output impedance is approximately 50 Ω. A typically 50 Ω coaxial cable **50** couples device **60** to a transceiver **70** or other active or passive electronic equipment **70**.

As used herein, the term transceiver shall mean a piece of electronic equipment that can transmit, receive, or transmit and receive an electromagnetic signal via an antenna, such as the quad antenna shown in FIGS. **5**A or **5**B. As such, the term transceiver includes without limitation a transmitter, a receiver, a transmitter-receiver, a cellular telephone, a wireless telephone, a pager, a wireless computer local area network ("LAN") communicator, a passive resonant unit used by stores as part of an anti-theft system in which transceiver **70** contains a resonant circuit that is blown or not-blown by an electronic signal at time of purchase of the item to which transceiver **70** is affixed, resonant sensors and transponders, and the like.

Further, since antennas according to the present invention can receive incoming radiation and coupled the same as alternating current into a cable, it will be appreciated that fractal antennas may be used to intercept incoming light radiation and to provide a corresponding alternating current. For example, a photocell antenna defining a fractal, or indeed a plurality or array of fractals, would be expected to output more current in response to incoming light than would a photocell of the same overall array size. FIG. **5**B depicts a fractal quad antenna **95**, designed to resonant at the same frequency as the larger prior art antenna **5** shown in FIG. **5**A. Driven element **100** is seen to be a second order fractal, here a so-called Minkowski island fractal, although any of numerous other fractal configurations could instead be used, including without limitation, Koch, torn square, Mandelbrot, Caley tree, monkey's swing, Sierpinski gasket, and Cantor gasket geometry.

If one were to measure to the amount of conductive wire or conductive trace comprising the perimeter of element **10** or element **20**, it would be perhaps 40% greater than the 1.0 λ for the Euclidean quad of FIG. **5**A. However, for fractal antenna **95**, the physical straight length of one element side KS will be substantially smaller, and for the N=2 fractal antenna shown in FIG. **5**B, KS≈0.13 λ (in air), compared with K≈0.25 λ for prior art antenna **5**.

However, although the actual perimeter length of element **100** is greater than the 1 λ perimeter of prior art element **10**, the area within antenna element **100** is substantially less than the S^2 area of prior art element **10**. As noted, this area independence from perimeter is a characteristic of a deterministic fractal. Boom length B for antenna **95** will be slightly different from length B for prior art antenna **5** shown in FIG. **5**A. In FIG. **5**B, a parasitic element **120**, which preferably is similar to driven element **100** but need not be, may be attached to boom **130**. For ease of illustration FIG. **5**B does not depict non-conductive spreaders, such as spreaders **40** shown in FIG. **5**A, which help hold element **100** together and element **120** together. Further, for ease of understanding the figure, element **10** is drawn with heavier lines than element **120**, to avoid confusion in the portion of the figure in which elements **100** and **120** appear overlapped.

An impedance matching device **60** is advantageously unnecessary for the fractal antenna of FIG. **5**B, as the driving impedance of element **100** is about 50 Ω, e.g., a perfect match for cable **50** if reflector element **120** is absent, and about 35 Ω, still an acceptable impedance match for cable **50**, if element **120** is present. Antenna **95** may be fed by cable **50** essentially anywhere in element **100**, e.g., including locations X, Y, Z, among others, with no substantial change in the termination impedance. With cable **50** connected as shown, antenna **95** will exhibit horizontal polarization. If vertical polarization is desired, connection may be made as shown by cable **50**'. If desired, cables **50** and **50**' may both be present, and an electronic switching device **75** at the antenna end of these cables can short-out one of the cables. If cable **50** is shorted out at the antenna, vertical polarization results, and if instead cable **50**' is shorted out at the antenna, horizontal polarization results.

As shown by Table 3 herein, fractal quad **95** exhibits about 1.5 dB gain relative to Euclidean quad **10**. Thus, transmitting power output by transceiver **70** may be cut by perhaps 40% and yet the system of FIG. **5**B will still perform no worse than the prior art system of FIG. **5**A. Further, as shown by Table 1, the fractal antenna of FIG. **5**B exhibits more resonance frequencies than the antenna of FIG. **5**B, and also exhibits some resonant frequencies that are not harmonically related to each other. As shown by Table 3, antenna **95** has efficiency exceeding about 92% and exhibits an excellent SWR of about 1.2:1. As shown by Table 5, applicant's fractal quad antenna exhibits a relatively low value of Q. This result is surprising in view of conventional prior art wisdom to the effect that small loop antennas will exhibit high Q.

In short, that fractal quad **95** works at all is surprising in view of the prior art (mis)understanding as to the nature of radiation resistance R and ohmic losses O. Indeed, the prior art would predict that because the fractal antenna of FIG. **5**B is smaller than the conventional antenna of FIG. **5**A, efficiency would suffer due to an anticipated decrease in radiation resistance R. Further, it would have been expected that Q would be unduly high for a fractal quad antenna.

FIG. **6** is an ELNEC-generated free-space radiation pattern for a second-iteration Minkowski fractal antenna, an antenna similar to what is shown in FIG. **5**B with the parasitic element **120** omitted. The frequency of interest was 42.3 MHz, and a 1.5:1 SWR was used. In FIG. **6**, the outer ring represents 2.091 dBi, and a maximum gain of 2.091 dBi. (ELNEC is a graphics/PC version of MININEC, which is a PC version of NEC.) In practice, however, the data shown in FIG. **6** were conservative in that a gain of 4.8 dB above an isotropic reference radiator was actually obtained. The error in the gain figures associated with FIG. **6** presumably is due to roundoff and other limitations inherent in the ELNEC program. Nonetheless, FIG. **6** is believed to accurately depict the relative gain radiation pattern of a single element Minkowski (MI-2) fractal quad according to the present invention.

FIG. **7**A depicts a third iteration Cantor-comb fractal dipole antenna, according to the present invention. Generation of a Cantor-comb involves trisecting a basic shape, e.g., a rectangle, and providing a rectangle of one-third of the basic shape on the ends of the basic shape. The new smaller rectangles are then trisected, and the process repeated. FIG. **7**B is modelled after the Lauwerier treatise, and depicts a single element torn-sheet fractal quad antenna.

As described later herein, the fractal element shown in FIG. **7**B may be used as a ground counterpoise for an antenna system, for example, for a vertical antenna. In such application, the center conductor of cable **50** would be coupled to the lower end of the vertical antenna element (not shown, but which itself may be a fractal), and the ground shield of cable **50** would be coupled to the fractal element shown in FIG. **7**B. The fractal groundpoise may be substantially smaller than a conventional 0.25 λ ground system, without detriment to gain, coupling impedance, and vertical polarization characteristics of the antenna system.

FIG. **7C-1** depicts a printed circuit antenna, in which the antenna is fabricated using printed circuit or semiconductor fabrication techniques. For ease of understanding, the etched-away non-conductive portion of the printed circuit board **150** is shown cross-hatched, and the copper or other conductive traces **170** are shown without cross-hatching.

Applicant notes that while various corners of the Minkowski rectangle motif may appear to be touching in this and perhaps other figures herein, in fact no touching occurs. Further, it is understood that it suffices if an element according to the present invention is substantially a fractal. By this it is meant that a deviation of less than perhaps 10% from a perfectly drawn and implemented fractal will still provide adequate fractal-like performance, based upon actual measurements conducted by applicant.

The substrate **150** is covered by a conductive layer of material **170** that is etched away or otherwise removed in areas other than the fractal design, to expose the substrate **150**. The remaining conductive trace portion **170** defines a fractal antenna, a second iteration Minkowski slot antenna in FIG. **7C-1**. Substrate **150** may be a silicon wafer, a rigid or a flexible plastic-like material, perhaps Mylar™ material, or the non-conductive portion of a printed circuit board. Overlayer **170** may be deposited doped polysilicon for a semiconductor substrate **150**, or copper for a printed circuit board substrate.

If desired, the fractal structure shown in FIG. **7C-1** could be utilized as a fractal ground counterpoise for an antenna system, for example a vertical antenna. The fractal ground counterpoise may be fabricated using smaller dimensions than a conventional prior art system employing typically 0.25 λ ground radials or elements. If the structure shown in FIG. **7C-1** is used as a ground counterpoise, the center lead of cable **50** would be coupled to the vertical element (not shown), and the ground shield would be coupled to the fractal structure shown.

FIG. **7C-2** depicts a slot antenna version of what was shown in FIG. **7C-2**, wherein the conductive portion **170** (shown cross-hatched in FIG. **7C-2**) surrounds and defines a fractal-shape of non-conductive substrate **150**. Electrical connection to the slot antenna is made with a coaxial or other cable **50**, whose inner and outer conductors make contact as shown.

In FIGS. **7C-1** and **7C-2**, the substrate or plastic-like material in such constructions can contribute a dielectric effect that may alter somewhat the performance of a fractal antenna by reducing resonant frequency, which increases perimeter compression PC.

Those skilled in the art will appreciate that by virtue of the relatively large amount of conducting material (as contrasted to a thin wire), antenna efficiency is promoted in a slot configuration. Of course a printed circuit board or substrate-type construction could be used to implement a non-slot fractal antenna, e.g, in which the fractal motif is fabricated as a conductive trace and the remainder of the conductive material is etched away or otherwise removed. Thus, in FIG. **7C-1**, for example, if the cross-hatched surface now represents non-conductive material, and the non-cross hatched material represents conductive material, a printed circuit board or substrate-implemented wire-type fractal antenna results.

Printed circuit board and/or substrate-implemented fractal antennas are especially useful at frequencies of 80 MHz or higher, whereat fractal dimensions indeed become small. A 2 M MI-3 fractal antenna (e.g., FIG. **7**E) will measure about 5.5" (14 cm) on a side KS, and an MI-2 fractal antenna (e.g., FIG. **5**B) will be about 7" (17.5 cm) per side KS. As will be seen from FIG. **9**A, an MI-3 antenna suffers a slight loss in gain relative to an MI-2 antenna, but offers substantial size reduction.

Applicant has fabricated an MI-2 Minkowski island fractal antenna for operation in the 850–900 MHz cellular telephone band. The antenna was fabricated on a printed circuit board and measured about 1.2" (3 cm) on a side KS. The antenna was sufficiently small to fit inside applicant's cellular telephone, and performed as well as if the normal attachable "rubber-ducky" whip antenna were still attached. The antenna was found on the side to obtain desired vertical polarization, but could be fed anywhere on the element with 50 Ω impedance still being inherently present. Applicant also fabricated on a printed circuit board an MI-3 Minkowski island fractal quad, whose side dimension KS was about 0.8" (2 cm), the antenna again being inserted inside the cellular telephone. The MI-3 antenna appeared to work as well as the normal whip antenna, which was not attached. Again, any slight gain loss in going from MI-2 to MI-3 (e.g., perhaps 1 dB loss relative to an MI-0 reference quad, or 3 dB los relative to an MI-2) is more than offset by the resultant shrinkage in size. At satellite telephone frequencies of 1650 MHz or so, the dimensions would be approximately halved again. FIGS. **8**A, **8**B and **8**C depict preferred embodiments for such antennas.

FIG. **7**D depicts a 2 M dendrite deterministic fractal antenna that includes a slight amount of randomness. The vertical arrays of numbers depict wavelengths relative to 0 λ, at the lower end of the trunk-like element **200**. Eight radial-like elements **210** are disposed at 1.0 λ, and various other elements are disposed vertically in a plane along the length of element **200**. The antenna was fabricated using 12 gauge copper wire and was found to exhibit a surprising 20 dBi gain, which is at least 10 dB better than any antenna twice the size of what is shown in FIG. **7**D. Although superficially the vertical of FIG. **7**D may appear analogous to a log-periodic antenna, a fractal vertical according to the present invention does not rely upon an opening angle, in stark contrast to prior art log periodic designs.

FIGS. **7**D-**1**A and **7**D-**1**B depict a conventional vertical antenna **5**, comprising a 0.25 λ long vertical element **195**, and three 0.25 λ long ground plane radials **205**. Antenna **5** is fed using coaxial cable **50** in conventional fashion, the antenna impedance being on the order of about 24 Ω. Antenna efficiency may be improved by adding additional radial elements **205**, however doing so frequently requires more space than is conveniently available. In other configurations, a ground plane or counterpoise may be used without radials, e.g., earth or the metal body of an automobile in the case of a vehicular-mounted antenna. The 0° elevation angle azimuth plot of FIG. **7**D-**1**B depicts the undesirably large horizontal polarization components (the "figure eight" pattern) exhibited by this prior art vertical system, with vertical and total gain being about 1.45 dBi.

FIG. **7**D-**2**A depicts an antenna system **5** according to the present invention as including a vertical element **195** and a fractalized ground counterpoise system comprising, in this example, three dendrite fractal ground radials **215**. The ground radials are coupled to the ground shield on cable **50**, whereas the center lead of cable **50** is coupled to the vertical element **195**. Of course, other fractal configurations may be used instead, and a different number of ground radials may also be used.

In the azimuth plot of FIG. **7**D-**2**B, the elevation angle is 0°, and each fractal ground radial element is only about 0.087 λ. The maximum gain, at the outermost ring in the figure, is 1.83 dBi and the input impedance is about 30 Ω. Note in FIG. **7**D-**2**B that relatively little energy is radiated horizontally, and nearly all of the energy is radiated vertically, a desirable characteristic for a vertical antenna. It will be appreciated that the 0.087 λ dimensions of fractal ground plane elements **215** are substantially physically smaller than the 0.25 λ elements **205** in the prior art system of FIG. **7**D-**1**A. However, the radiation pattern for the system of FIG. **7**D-**2**A is actually better than that of the larger prior art system.

FIG. **7**D-**3**A depicts a so-called "top-hat" loaded vertical antenna **5**, according to the prior art. Antenna **5** includes a vertical element **195** and, in the example shown, a top-hat assembly comprising three spokes **207** located at the antenna top. The antenna is fed in conventional fashion with coaxial cable **50**. FIG. **7**D-**3**B depicts the radiation pattern for the conventional top-hat loaded antenna of FIG. **7**D-**3**A.

FIG. **7**D-**4**A depicts a "top-hat" antenna **5** that includes a vertical element **195** whose top is loaded by a top-hat assembly including fractalized radial spokes **215**. Antenna **5** may be fed in conventional fashion by coaxial cable **50**. For the same vertical length of element **195** as was used in FIG. **7**D-**3**A, the use of fractal radial spokes **215** advantageously decreases resonant frequency by 20%. In addition, the size of the "top-hat" assembly may be reduced by about 20%, and the area required for the "top-hat" assembly may be reduced by about 35%. These reductions are advantageous in that the fractalized top-hat antenna of FIG. **7**D-**4**A can require less material to fabricate, thus reducing manufacturing cost, weight, and wind resistance, relative to a prior art top-hat configuration. According to the present invention, it suffices if at least one of the elements in the top-hat assembly has a physical shaped defined at least in part by a fractal. Of course, more or less than three spokes may be used, and other fractal configurations may also be used, including combinations of fractal and non-fractal elements, as well as different types of fractal elements.

FIG. **7**D-**4**B represents the radiation pattern for the fractalized top-hat antenna of FIG. **7**D-**4**A. A comparison of FIGS. **7**D-**4**B and **7**D-**3**B confirms that there is no real performance penalty associated with using the fractalized configuration. Thus, the above-noted savings in cost, weight, and wind resistance are essentially penalty free.

FIG. **7**D-**5** depicts an antenna system according to the present invention, in which fractal ground elements **215** and a fractal vertical element **197** are both used. Fractal antenna elements **215** are preferably about 0.087 λ, and element **197** is about λ/12. Fractal vertical element **197** preferably comprises a pair of spaced-apart elements such as generally described with respect to FIGS. **11**A, **12**A, **12**B, **13**B, **14**A, **14**B, and **14**C. It is to be understood, however, that the salient feature of element **197** in FIG. **7**D-**3** is not its specific shape, but rather that it defines a fractal, and preferably a pair of spaced-apart fractal elements. It is solely for ease of illustration that the fractal elements shown in FIGS. **7**D-**3**, **11**A, **12**A, **12**B, **13**B, **14**A, **14**B, **14**C, and **14**D are similarly drawn. Further, the fractal—fractal antenna system shown in FIG. **7**D-**3** is preferably tuned by varying the spaced-apart distance Δ, and/or by rotating the spaced-apart elements relative to one another, and/or by forming a "cut" in an element, as described hereinafter with respect to various of FIGS. **11**A, **12**A, **12**B, **13**B, **14**A, **14**B, **14**C and **14**D.

FIG. **7**E depicts a third iteration Minkowski island quad antenna (denoted herein as MI-3). The orthogonal line segments associated with the rectangular Minkowski motif make this configuration especially acceptable to numerical study using ELNEC and other numerical tools using moments for estimating power patterns, among other modelling schemes. In testing various fractal antennas, applicant formed the opinion that the right angles present in the Minkowski motif are especially suitable for electromagnetic frequencies.

With respect to the MI-3 fractal of FIG. 7E, applicant discovered that the antenna becomes a vertical if the center led of coaxial cable **50** is connected anywhere to the fractal, but the outer coaxial braid-shield is left unconnected at the antenna end. (At the transceiver end, the outer shield is connected to ground.) Not only do fractal antenna islands perform as vertical antennas when the center conductor of cable **50** is attached to but one side of the island and the braid is left ungrounded at the antenna, but resonance frequencies for the antenna so coupled are substantially reduced. For example, a 2" (5 cm) sized MI-3 fractal antenna resonated at 70 MHz when so coupled, which is equivalent to a perimeter compression PC≈20.

FIG. **7**F depicts a second iteration Koch fractal dipole, and FIG. **7**G a third iteration dipole. FIG. **7**H depicts a second iteration Minkowski fractal dipole, and FIG. **7**I a third iteration multi-fractal dipole. Depending upon the frequencies of interest, these antennas may be fabricated by bending wire, or by etching or otherwise forming traces on a substrate. Each of these dipoles provides substantially 50 Ω termination impedance to which coaxial cable **50** may be directly coupled without any impedance matching device. It is understood in these figures that the center conductor of cable **50** is attached to one side of the fractal dipole, and the braid outer shield to the other side.

A fractal ground counterpoise may be fabricated using fractal element as shown in any (or all) of FIGS. 7E–7I. Thus, in FIGS. 7D-2A and 7D-**3**, fractal ground radial elements **215** are understood to depict any fractal of iteration order N≧1. Further, such fractals may, but need not be, defined by an opening angle.

FIG. **8**A depicts a generalized system in which a transceiver **500** is coupled to a fractal antenna system **510** to send electromagnetic radiation **520** and/or receive electromagnetic radiation **540**. A second transceiver **600** shown equipped with a conventional whip-like vertical antenna **610** also sends electromagnetic energy **630** and/or receives electromagnetic energy **540**.

Fractal antenna system **510** may include a fractal ground counterpoise and/or fractal antenna element, as described earlier herein. As noted in the case of a vertical antenna element, the overall size of the resulting antenna system is substantially smaller than what may be achieved with a prior art ground counterpoise system. Further, the fractal ground counterpoise system may be fabricated on a flexible substrate that is rolled or otherwise formed to fit within a case such as contains transceiver **500**. The resultant antenna ground system exhibits improved efficiency and power distribution pattern relative to a prior art system that may somehow be fit into an equivalent amount of area.

If transceivers **500, 600** are communication devices such as transmitter-receivers, wireless telephones, pagers, or the like, a communications repeating unit such as a satellite **650** and/or a ground base repeater unit **660** coupled to an antenna **670**, or indeed to a fractal antenna according to the present invention, may be present.

Alteratively, antenna **510** in transceiver **500** could be a passive LC resonator fabricated on an integrated circuit microchip, or other similarly small sized substrate, attached to a valuable item to be protected. Transceiver **600,** or indeed unit **660** would then be an electromagnetic transmitter outputting energy at the frequency of resonance, a unit typically located near the cash register checkout area of a store or at an exit. Depending upon whether fractal antenna-resonator **510** is designed to "blow" (e.g., become open circuit) or to "short" (e.g., become a close circuit) in the transceiver **500** will or will not reflect back electromagnetic energy **540** or **630** to a receiver associated with transceiver **600**. In this fashion, the unauthorized relocation of antenna **510** and/or transceiver **500** can be signalled by transceiver **600**.

FIG. **8**B depicts a transceiver **500** equipped with a plurality of fractal antennas, here shown as **510A, 510B, 510C** and **510D** coupled by respective cables **50A, 50B, 50C, 50D** to electronics **600** within unit **500**. In the embodiment shown, one of more of these antenna elements is are fabricated on a conformal, flexible substrate **150**, e.g., Mylar™ material or the like, upon which the antennas per se may be implemented by printing fractal patterns using conductive ink, by copper deposition, among other methods including printed circuit board and semiconductor fabrication techniques. A flexible such substrate may be conformed to a rectangular, cylindrical or other shape as necessary.

In the embodiment of FIG. **8**B, unit **500** is a handheld transceiver, and antennas **510A, 510B, 510C, 510D** preferably are fed for vertical polarization, as shown. Element **510D** may, for example, be a fractal ground counterpoise system for a vertical antenna element, shown in phantom as element **193** (which element may itself be a fractal to further reduce dimensions).

An electronic circuit **615** is coupled by cables **50A, 50B, 50C** to the antennas, and samples incoming signals to discern which fractal antenna system, e.g., **510A, 510B, 510C, 510D** is presently most optimally aligned with the transmitting station, perhaps a unit **600** or **650** or **660** as shown in FIG. **8**A. This determination may be made by examining signal strength from each of the antennas. An electronic circuit **620** then selects the presently best oriented antenna, and couples such antenna to the input of the receiver and output of the transmitter portion, collectively **630,** of unit **500**. It is understood that the selection of the best antenna is dynamic and can change as, for example, a user of **500** perhaps walks about holding the unit, or the transmitting source moves, or due to other changing conditions. In a cellular or a wireless telephone application, the result is more reliable communication, with the advantage that the fractal antennas can be sufficiently small-sized as to fit totally within the casing of unit **500**. Further, if a flexible substrate is used, the antennas may be wrapped about portions of the internal casing, as shown.

An additional advantage of the embodiment of FIG. **8**B is that the user of unit **500** may be physically distanced from the antennas by a greater distance that if a conventional external whip antenna were used. Although medical evidence attempting to link cancer with exposure to electromagnetic radiation from handheld transceivers is still inconclusive, the embodiment of FIG. **8**B appears to minimize any such risk. Although FIG. **8**B depicts a vertical antenna **193** and a fractal ground counterpoise **510D**, it is understood that antenna **193** could represent a cellular antenna on a motor vehicle, the groundpoise for which is fractal unit **510D**. Further, as noted, vertical element **193** may itself be a fractal.

FIG. **8**C depicts yet another embodiment wherein some or all of the antenna systems **510A, 510B, 510C** may include electronically steerable arrays, including arrays of fractal antennas of differing sizes and polarization orientations. Antenna system **510C**, for example may include similarly designed fractal antennas, e.g., antenna F-**3** and F-**4**, which are differently oriented from each other. Other antennas within system **510C** may be different in design from either of F-**3**, F-**4**. Fractal antenna F-**1** may be a dipole for example. Leads from the various antennas in system **510C** may be coupled to an integrated circuit **690**, mounted on substrate

150. Circuit **690** can determine relative optimum choice between the antennas comprising system **510**C, and output via cable **50**C to electronics **600** associated with the transmitter and/or receiver portion **630** of unit **630**. Of course, the embodiment of FIG. **8**C could also include the vertical antenna element **193** and fractal ground counterpoise **510**D, depicted in FIG. **8**B.

Another antenna system **510**B may include a steerable array of identical fractal antennas, including fractal antenna F-**5** and F-**6**. An integrated circuit **690** is coupled to each of the antennas in the array, and dynamically selects the best antenna for signal strength and coupled such antenna via cable **50**B to electronics **600**. A third antenna system **510**A may be different from or identical to either of system **510**B and **510**C.

Although FIG. **8**C depicts a unit **500** that may be handheld, unit **500** could in fact be a communications system for use on a desk or a field mountable unit, perhaps unit **660** as shown in FIG. **8**A.

For ease of antenna matching to a transceiver load, resonance of a fractal antenna was defined as a total impedance falling between about 20 Ω to 200 Ω, and the antenna was required to exhibit medium to high Q, e.g., frequency/Δfrequency. In practice, applicants' various fractal antennas were found to resonate in at least one position of the antenna feedpoint, e.g., the point at which coupling was made to the antenna. Further, multi-iteration fractals according to the present invention were found to resonate at multiple frequencies, including frequencies that were non-harmonically related.

Contrary to conventional wisdom, applicant found that island-shaped fractals (e.g., a closed loop-like configuration) do not exhibit significant drops in radiation resistance R for decreasing antenna size. As described herein, fractal antennas were constructed. with dimensions of less than 12" across (30.48 cm) and yet resonated in a desired 60 MHz to 100 MHz frequency band.

Applicant further discovered that antenna perimeters do not correspond to lengths that would be anticipated from measured resonant frequencies, with actual lengths being longer than expected. This increase in element length appears to be a property of fractals as radiators, and not a result of geometric construction. A similar lengthening effect was reported by Pfeiffer when constructing a full-sized quad antenna using a first order fractal, see A. Pfeiffer, *The Pfeiffer Quad Antenna System*, QST, p. 28–32 (March 1994).

If L is the total initial one-dimensional length of a fractal pre-motif application, and r is the one-dimensional length post-motif application, the resultant fractal dimension D (actually a ratio limit) is:

$$D=\log(L)/\log(r)$$

With reference to FIG. **1**A, for example, the length of FIG. **1**A represents L, whereas the sum of the four line segments comprising the Koch fractal of FIG. **1**B represents r.

Unlike mathematical fractals, fractal antennas are not characterized solely by the ratio D. In practice D is not a good predictor of how much smaller a fractal design antenna may be because D does not incorporate the perimeter lengthening of an antenna radiating element.

Because D is not an especially useful predictive parameter in fractal antenna design, a new parameter "perimeter compression" ("PC") shall be used, where:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

In above equation, measurements are made at the fractal-resonating element's lowest resonant frequency. Thus, for a full-sized antenna according to the prior art PC=1, while PC=3 represents a fractal antenna according to the present invention, in which an element side has been reduced by a factor of three.

Perimeter compression may be empirically represented using the fractal dimension D as follows:

$$PC=A\cdot\log[N(D+C)]$$

where A and C are constant coefficients for a given fractal motif, N is an iteration number, and D is the fractal dimension, defined above.

It is seen that for each fractal, PC becomes asymptotic to a real number and yet does not approach infinity even as the iteration number N becomes very large. Stated differently, the PC of a fractal radiator asymptotically approaches a non-infinite limit in a finite number of fractal iterations. This result is not a representation of a purely geometric fractal.

That some fractals are better resonating elements than other fractals follows because optimized fractal antennas approach their asymptotic PCs in fewer iterations than non-optimized fractal antennas. Thus, better fractals for antennas will have large values for A and C, and will provide the greatest and most rapid element-size shrinkage. Fractal used may be deterministic or chaotic. Deterministic fractals have a motif that replicates at a 100% level on all size scales, whereas chaotic fractals include a random noise component.

Applicant found that radiation resistance of a fractal antenna decreases as a small power of the perimeter compression (PC), with a fractal island always exhibiting a substantially higher radiation resistance than a small Euclidean loop antenna of equal size.

Further, it appears that the number of resonant nodes of a fractal island increase as the iteration number (N) and is always greater than or equal to the number of resonant nodes of an Euclidean island with the same area. Finally, it appears that a fractal resonator has an increased effective wavelength.

The above findings will now be applied to experiments conducted by applicant with fractal resonators shaped into closed-loops or islands. Prior art antenna analysis would predict no resonance points, but as shown below, such is not the case.

A Minkowski motif is depicted in FIGS. **2**B–**2**D, **5**B, **7**C and **7**E. The Minkowski motif selected was a three-sided box (e.g., **20-2** in FIG. **2**B) placed atop a line segment. The box sides may be any arbitrary length, e.g, perhaps a box height and width of 2 units with the two remaining base sides being of length three units (see FIG. **2**B). For such a configuration, the fractal dimension D is as follows:

$$D = \frac{\log(L)}{\log(r)} = \frac{\log(12)}{\log(8)} = \frac{1.08}{0.90} = 1.20$$

It will be appreciated that D=1.2 is not especially high when compared to other deterministic fractals.

Applying the motif to the line segment may be most simply expressed by a piecewise function f(x) as follows:

$$f(x)=0 \qquad 0 \geq x \geq \frac{3x_{\max}}{8}$$

$$f(x)=\frac{1}{4x_{\max}} \qquad \frac{3x_{\max}}{8} \geq x \geq \frac{5x_{\max}}{8}$$

$$f(x)=0 \qquad \frac{5x_{\max}}{8} \geq x \geq x_{\max}$$

where x_{max} is the largest continuous value of x on the line segment.

A second iteration may be expressed as $f(x)_2$ relative to the first iteration $f(x)_1$ by:

$$f(x)_2=f(x)_1+f(x)$$

where x_{max} is defined in the above-noted piecewise function. Note that each separate horizontal line segment will have a different lower value of x and x_{max}. Relevant offsets from zero may be entered as needed, and vertical segments may be "boxed" by 90° rotation and application of the above methodology.

As shown by FIGS. **5**B and **7**E, a Minkowski fractal quickly begins to appear like a Moorish design pattern. However, each successive iteration consumes more perimeter, thus reducing the overall length of an orthogonal line segment. Four box or rectangle-like fractals of the same iteration number N may be combined to create a Minkowski fractal island, and a resultant "fractalized" cubical quad.

An ELNEC simulation was used as a guide to far-field power patterns, resonant frequencies, and SWRs of Minkowski Island fractal antennas up to iteration N=2. Analysis for N>2 was not undertaken due to inadequacies in the test equipment available to applicant.

The following tables summarize applicant's ELNEC simulated fractal antenna designs undertaken to derive lowest frequency resonances and power patterns, to and including iteration N=2. All designs were constructed on the x,y axis, and for each iteration the outer length was maintained at 42" (106.7 cm).

Table 1, below, summarizes ELNEC-derived far field radiation patterns for Minkowski island quad antennas for each iteration for the first four resonances. In Table 1, each iteration is designed as MI-N for Minkowski Island of iteration N. Note that the frequency of lowest resonance decreased with the fractal Minkowski Island antennas, as compared to a prior art quad antenna. Stated differently, for a given resonant frequency, a fractal Minkowski Island antenna will be smaller than a conventional quad antenna.

TABLE 1

Antenna	Res. Freq. (MHz)	Gain (dBi)	SWR	PC (for 1st)	Direction
Ref. Quad	76	3.3	2.5	1	Broadside
	144	2.8	5.3	—	Endfire
	220	3.1	5.2	—	Endfire
	294	5.4	4.5	—	Endfire
MI-1	55	2.6	1.1	1.38	Broadside
	101	3.7	1.4	—	Endfire
	142	3.5	5.5	—	Endfire
	198	2.7	3.3	—	Broadside
MI-2	43.2	2.1	1.5	1.79	Broadside
	85.5	4.3	1.8	—	Endfire
	102	2.7	4.0	—	Endfire
	116	1.4	5.4	—	Broadside

It is apparent from Table 1 that Minkowski island fractal antennas are multi-resonant structures having virtually the same gain as larger, full-sized conventional quad antennas. Gain figures in Table 1 are for "free-space" in the absence of any ground plane, but simulations over a perfect ground at 1 λ yielded similar gain results. Understandably, there will be some inaccuracy in the ELNEC results due to round-off and undersampling of pulses, among other factors.

Table 2 presents the ratio of resonant ELNEC-derived-frequencies for the first four resonance nodes referred to in Table 1.

TABLE 2

Antenna	SWR	SWR	SWR	SWR
Ref. Quad (MI-0)	1:1	1:1.89	1:2.89	3.86:1
MI-1	1:1	1:1.83	1;2.58	3.6:1
MI-2	1:1	2.02:1	2.41:1	2.74:1

Tables 1 and 2 confirm the shrinking of a fractal-designed antenna, and the increase in the number of resonance points. In the above simulations, the fractal MI-2 antenna exhibited four resonance nodes before the prior art reference quad exhibited its second resonance. Near fields in antennas are very important, as they are combined in multiple-element antennas to achieve high gain arrays. Unfortunately, programming limitations inherent in ELNEC preclude serious near field investigation. However, as described later herein, applicant has designed and constructed several different high gain fractal arrays that exploit the near field.

Applicant fabricated three Minkowski Island fractal antennas from aluminum #8 and/or thinner #12 galvanized groundwire. The antennas were designed so the lowest operating frequency fell close to a desired frequency in the 2 M (144 MHz) amateur radio band to facilitate relative gain measurements using 2 M FM repeater stations. The antennas were mounted for vertical polarization and placed so their center points were the highest practical point above the mounting platform. For gain comparisons, a vertical ground plane having three reference radials, and a reference quad were constructed, using the same sized wire as the fractal antenna being tested. Measurements were made in the receiving mode.

Multi-path reception was minimized by careful placement of the antennas. Low height effects were reduced and free space testing approximated by mounting the antenna test platform at the edge of a third-store window, affording a 3.5 λ height above ground, and line of sight to the repeater, 45 miles (28 kM) distant. The antennas were stuck out of the window about 0.8 λ from any metallic objects and testing was repeated on five occasions from different windows on the same floor, with test results being consistent within ½ dB for each trial.

Each antenna was attached to a short piece of 9913 50 Ω coaxial cable, fed at right angles to the antenna. A 2 M transceiver was coupled with 9913 coaxial cable to two precision attenuators to the antenna under test. The transceiver S-meter was coupled to a volt-ohm meter to provide signal strength measurements The attenuators were used to insert initial threshold to avoid problems associated with non-linear S-meter readings, and with S-meter saturation in the presence of full squelch quieting.

Each antenna was quickly switched in for volt-ohmmeter measurement,with attenuation added or subtracted to obtain the same meter reading as experienced with the reference quad. All readings were corrected for SWR attenuation. For the reference quad, the SWR was 2.4:1 for 120 Ω impedance, and for the fractal quad antennas SWR was less than 1.5:1 at resonance. The lack of a suitable noise bridge for 2 M precluded efficiency measurements for the various antennas. Understandably, anechoic chamber testing would provide even more useful measurements.

For each antenna, relative forward gain and optimized physical orientation were measured. No attempt was made to correct for launch-angle, or to measure power patterns other than to demonstrate the broadside nature of the gain. Difference of ½ dB produced noticeable S-meter deflections, and differences of several dB produced substantial meter deflection. Removal of the antenna from the receiver resulted in a 20^+ dB drop in received signal strength. In this fashion, system distortions in readings were cancelled out to provide more meaningful results. Table 3 summarizes these results.

TABLE 3

Antenna	PC	PL	SWR	Cor. Gain (dB)	Sidelength (λ)
Quad	1	1	2.4:1	0	0.25
¼ wave	1	—	1.5:1	−1.5	0.25
MI-1	1.3	1.2	1.3:1	1.5	0.13
MI-2	1.9	1.4	1.3:1	1.5	0.13
MI-3	2.4	1.7	1:1	−1.2	0.10

It is apparent from Table 3 that for the vertical configurations under test, a fractal quad according to the present invention either exceeded the gain of the prior art test quad, or had a gain deviation of not more than 1 dB from the test quad. Clearly, prior art cubical (square) quad antennas are not optimized for gain. Fractally shrinking a cubical quad by a factor of two will increase the gain, and further shrinking will exhibit modest losses of 1–2 dB.

Versions of a MI-2 and MI-3 fractal quad antennas were constructed for the 6 M (50 MHz) radio amateur band. An RX 50 Ω noise bridge was attached between these antennas and a transceiver. The receiver was nulled at about 54 MHz and the noise bridge was calibrated with 5 Ω and 10 Ω resistors. Table 4 below summarizes the results, in which almost no reactance was seen.

TABLE 4

Antenna	SWR	Z (Ω)	O (Ω)	E (%)
Quad (MI-0)	2.4:1	120	5–10	92–96
MI-2	1.2:1	60	≦5	≧92
MI-3	1.1:1	55	≦5	≧91

In Table 4, efficiency (E) was defined as 100%*(R/Z), where Z was the measured impedance, and R was Z minus ohmic impedance and reactive impedances (0). As shown in Table 4, fractal MI-2 and MI-3 antennas with their low ≦1.2:1 SWR and low ohmic and reactive impedance provide extremely high efficiencies, 90^+%. These findings are indeed surprising in view of prior art teachings stemming from early Euclidean small loop geometries. In fact, Table 4 strongly suggests that prior art associations of low radiation impedances for small loops must be abandoned in general, to be invoked only when discussing small Euclidean loops. Applicant's MI-3 antenna was indeed micro-sized, being dimensioned at about 0.1 λ per side, an area of about $\lambda^2/1,000$, and yet did not signal the onset of inefficiency long thought to accompany smaller sized antennas.

However the 6M efficiency data do not explain the fact that the MI-3 fractal antenna had a gain drop of almost 3 dB relative to the MI-2 fractal antenna. The low ohmic impedances of ≦5 Ω strongly suggest that the explanation is other than inefficiency, small antenna size notwithstanding. It is quite possible that near field diffraction effects occur at higher iterations that result in gain loss. However, the smaller antenna sizes achieved by higher iterations appear to warrant the small loss in gain.

Using fractal techniques, however, 2 M quad antennas dimensioned smaller than 3" (7.6 cm) on a side, as well as 20 M (14 MHz) quads smaller than 3' (1 m) on a side can be realized. Economically of greater interest, fractal antennas constructed for cellular telephone frequencies (850 MHz) could be sized smaller than 0.5" (1.2 cm). As shown by FIGS. **8**B and **8**C, several such antenna, each oriented differently could be fabricated within the curved or rectilinear case of a cellular or wireless telephone, with the antenna outputs coupled to a circuit for coupling to the most optimally directed of the antennas for the signal then being received. The resultant antenna system would be smaller than the "rubber-ducky" type antennas now used by cellular telephones, but would have improved characteristics as well.

Similarly, fractal-designed antennas could be used in handheld military walkie-talkie transceivers, global positioning systems, satellites, transponders, wireless communication and computer networks, remote and/or robotic control systems, among other applications.

Although the fractal Minkowski island antenna has been described herein, other fractal motifs are also useful, as well as non-island fractal configurations.

Table 5 demonstrates bandwidths ("BW") and multi-frequency resonances of the MI-2 and MI-3 antennas described, as well as Qs, for each node found for 6 M versions between 30 MHz and 175 MHz. Irrespective of resonant frequency SWR, the bandwidths shown are SWR 3:1 values. Q values shown were estimated by dividing resonant frequency by the 3:1 SWR BW. Frequency ratio is the relative scaling of resonance nodes.

TABLE 5

Antenna	Freq. (MHz)	Freq. Ratio	SWR	3:1 BW	Q
MI-3	53.0	1	1:1	6.4	8.3
	80.1	1.5:1	1.1:1	4.5	17.8
	121.0	2.3:1	2.4:1	6.8	17.7
MI-2	54.0	1	1:1	3.6	15.0
	95.8	1.8:1	1.1:1	7.3	13.1
	126.5	2.3:1	2.4:1	9.4	13.4

The Q values in Table 5 reflect that MI-2 and MI-3 fractal antennas are multiband. These antennas do not display the very high Qs seen in small tuned Euclidean loops, and there appears not to exist a mathematical application to electromagnetics for predicting these resonances or Qs. One approach might be to estimate scalar and vector potentials in Maxwell's equations by regarding each Minkowski Island iteration as a series of vertical and horizontal line segments with offset positions. Summation of these segments will lead to a Pointing vector calculation and power pattern that may be especially useful in better predicting fractal antenna characteristics and optimized shapes.

In practice, actual Minkowski Island fractal antennas seem to perform slightly better than their ELNEC predictions, most likely due to inconsistencies in ELNEC modelling or ratios of resonant frequencies, PCs, SWRs and gains.

Those skilled in the art will appreciate that fractal multiband antenna arrays may also be constructed. The resultant arrays will be smaller than their Euclidean counterparts, will present less wind area, and will be mechanically rotatable with a smaller antenna rotator.

Further, fractal antenna configurations using other than Minkowski islands or loops may be implemented. Table 6 shows the highest iteration number N for other fractal configurations that were found by applicant to resonant on at least one frequency.

FIG. **9**A depicts gain relative to an Euclidean quad (e.g., an MI-0) configuration as a function of iteration value N. (It is understood that an Euclidean quad exhibits 1.5 dB gain relative to a standard reference dipole.) For first and second order iterations, the gain of a fractal quad increases relative to an Euclidean quad. However, beyond second order, gain drops off relative to an Euclidean quad. Applicant believes that near field electromagnetic energy diffraction-type cancellations may account for the gain loss for N>2. Possibly the far smaller areas found in fractal antennas according to the present invention bring this diffraction phenomenon into sharper focus.

In practice, applicant could not physically bend wire for a 4th or 5th iteration 2 M Minkowski fractal antenna, although at lower frequencies the larger antenna sizes would not present this problem. However, at higher frequencies, printed circuitry techniques, semiconductor fabrication techniques as well as machine-construction could readily produce N=4, N=5, and higher order iterations fractal antennas.

In practice, a Minkowski island fractal antenna should reach the theoretical gain limit of about 1.7 dB seen for sub-wavelength Euclidean loops, but N will be higher than 3. Conservatively, however, an N=4 Minkowski Island fractal quad antenna should provide a PC=3 value without exhibiting substantial inefficiency.

FIG. **9**B depicts perimeter compression (PC) as a function of iteration order N for a Minkowski island fractal configuration. A conventional Euclidean quad (MI-0) has PC=1 (e.g., no compression), and as iteration increases, PC increases. Note that as N increases and approaches 6, PC approaches a finite real number asymptotically, as predicted. Thus, fractal Minkowski Island antennas beyond iteration N=6 may exhibit diminishing returns for the increase in iteration.

It will be appreciated that the non-harmonic resonant frequency characteristic of a fractal antenna according to the present invention may be used in a system in which the frequency signature of the antenna must be recognized to pass a security test. For example, at suitably high frequencies, perhaps several hundred MHz, a fractal antenna could be implemented within an identification credit card. When the card is used, a transmitter associated with a credit card reader can electronically sample the frequency resonance of the antenna within the credit card. If and only if the credit card antenna responds with the appropriate frequency signature pattern expected may the credit card be used, e.g., for purchase or to permit the owner entrance into an otherwise secured area.

FIG. **10**A depicts a fractal inductor L according to the present invention. In contrast to a prior art inductor, the winding or traces with which L is fabricated define, at least in part, a fractal. The resultant inductor is physically smaller than its Euclidean counterpart. Inductor L may be used to form a resonator, including resonators such as shown in FIGS. **4**A and **4**B. As such, an integrated circuit or other suitably small package including fractal resonators could be used as part of a security system in which electromagnetic radiation, perhaps from transmitter **600** or **660** in FIG. **8**A will blow, or perhaps not blow, an LC resonator circuit containing the fractal antenna. Such applications are described elsewhere herein and may include a credit card sized unit **700**, as shown in FIG. **10**B, in which an LC fractal resonator **710** is implemented. (Card **700** is depicted in FIG. **10**B as though its upper surface were transparent.).

The foregoing description has largely replicated what has been set forth in applicant's above-noted FRACTAL ANTENNAS AND FRACTAL RESONATORS patent application. The following section will set forth methods and techniques for tuning such fractal antennas and resonators. In the following description, although the expression "antenna" may be used in referring to a preferably fractal element, in practice what is being described is an antenna or filter-resonator system. As such, an "antenna" can be made to behave as through it were a filter, e.g., passing certain frequencies and rejecting other frequencies (or the converse).

In one group of embodiments, applicant has discovered that disposing a fractal antenna a distance Δ that is in close proximity (e.g., less than about 0.05 λ for the frequency of interest) from a conductor advantageously can change the resonant properties and radiation characteristics of the antenna (relative to such properties and characteristics when such close proximity does not exist, e.g., when the spaced-apart distance is relatively great. For example, in FIG. **11**A a conductive surface **800** is disposed a distance Δ behind or beneath a fractal antenna **810**, which in FIG. **11**A is a single arm of an MI-2 fractal antenna. Of course other fractal configurations such as disclosed herein could be used instead of the MI-1 configuration shown, and non-planar configurations may also be used. Fractal antenna **810** preferably is fed with coaxial cable feedline **50**, whose center conductor is attached to one end **815** of the fractal antenna, and whose outer shield is grounded to the conductive plane **800**. As described herein, great flexibility in connecting the antenna system shown to a preferably coaxial feedline exists. Termination impedance is approximately of similar magnitudes as described earlier herein.

In the configuration shown, the relative close proximity between conductive sheet **800** and fractal antenna **810** lowers the resonant frequencies and widens the bandwidth of antenna **810**. The conductive sheet **800** may be a plane of metal, the upper copper surface of a printed circuit board, a region of conductive material perhaps sprayed onto the housing of a device employing the antenna, for example the interior of a transceiver housing **500**, such as shown in FIGS. **8**A, **8**B, **8**C, and **15**.

The relationship between Δ, wherein $\Delta \leqq 0.05\ \lambda$, and resonant properties and radiation characteristics of a fractal antenna system is generally logarithmic. That is, resonant frequency decreases logarithmically with decreasing separation Δ.

FIG. **11**B shows an embodiment in which a preferably fractal antenna **810** lies in the same plane as a ground plane **800** but is separated therefrom by an insulating region, and in which a passive or parasitic element **800'** is disposed "within" and spaced-apart a distance Δ' from the antenna, and also being coplanar. For example, the embodiment of

FIG. **11**B may be fabricated from a single piece of printed circuit board material in which copper (or other conductive material) remains to define the groundplane **800**, the antenna **810**, and the parasitic element **800'**, the remaining portions of the original-material having been etched away to form the "moat-like" regions separating regions **800, 810**, and **800'**. changing the shape and/or size of element **800'** and/or the coplanar spaced-apart distance Δ' tunes the antenna system shown. For example, for a center frequency in the 900 MHz range, element **800'** measured about 63 mm×8 mm, and elements **810** and **800** each measured about 25 mm×12 mm. In general, element **800** should be at least as large as the preferably fractal antenna **810**. For this configuration, the system shown exhibited a bandwidth of about 200 MHz, and could be made to exhibit characteristics of a bandpass filter and/or band rejection filter. In this embodiment, a coaxial feedline **50** was used, in which the center lead was coupled to antenna **810**, and the ground shield lead was coupled to groundplane **800**. In FIG. **11**B, the inner perimeter of groundplane region **800** is shown as being rectangularly shaped. If desired, this inner perimeter could be moved closer to the outer perimeter of preferably fractal antenna **810**, and could in fact define a perimeter shape that follows the perimeter shape of antenna **810**. In such an embodiment, the perimeter of the inner conductive region **800'** and the inner perimeter of the ground plane region **800** would each follow the shape of antenna **810**. Based upon experiments to date, it is applicant's belief that moving the inner perimeter of ground plane region **800** sufficiently close to antenna **810** could also affect the characteristics of the overall antenna/resonator system.

Referring now to FIG. **12**A, if the conductive surface **800** is replaced with a second fractal antenna **810'**, which is spaced-apart a distance Δ that preferably does not exceed about 0.05 λ, resonances for the radiating fractal antenna **810** are lowered and advantageously new resonant frequencies emerge. For ease of fabrication, it may be desired to construct antenna **810** on the upper or first surface **820**A of a substrate **820**, and to construct antenna **810'** on the lower or second surface **820**B of the same substrate. The substrate could be doubled-side printed circuit board type material, if desired, wherein antennas **810, 810'** are fabricated using printed circuit type techniques. The substrate thickness Δ is selected to provide the desired performance for antenna **810** at the frequency of interest. Substrate **820** may, for example, be a non-conductive film, flexible or otherwise. To avoid cluttering FIGS. **12**A and **12**B, substrate **820** is drawn with phantom lines, as if the substrate were transparent.

As noted earlier, the fractal spaced-apart structure depicted in FIGS. **12**A and **12**B may instead be used to form a fractal element in a vertical antenna system, preferably including a fractal ground counterpoise, such as was described with respect to FIG. **8**D-**3**.

Preferably, the center conductor of coaxial cable **50** is connected to one end **815** of antenna **810**, and the outer conductor of cable **50** is connected to a free end **815'** of antenna **810'**, which is regarded as ground, although other feedline connections may be used. Although FIG. **12**A depicts antenna **810'** as being substantially identical to antenna **810**, the two antennas could in fact have different configurations.

Applicant has discovered that if the second antenna **810'** is rotated some angle θ relative to antenna **810**, the resonant frequencies of antenna **810** may be varied, analogously to tuning a variable capacitor. Thus, in FIG. **12**B, antenna **810** is tuned by rotating antenna **810'** relative to antenna **810** (or the converse, or by rotating each antenna). If desired, substrate **820** could comprise two substrates each having thickness Δ/2 and pivotally connected together, e.g., with a non-conductive rivet, so as to permit rotation of the substrates and thus relative rotation of the two antennas. Those skilled in the mechanical arts will appreciate that a variety of "tuning" mechanisms could be implemented to permit fine control over the angle θ in response, for example, to rotation of a tunable shaft.

Referring now to FIG. **13**A, applicant has discovered that creating at least one cut or opening **830** in a fractal antenna **810** (here comprising two legs of an MI-2 antenna) results in new and entirely different resonant nodes for the antenna. Further, these nodes can have perimeter compression (PC) ranging from perhaps three to about ten. The precise location of cut **830** on the fractal antenna or resonator does not appear to be critical.

FIGS. **13**B and **13**C depict a self-proximity characteristic of fractal antennas and resonators that may advantageously be used to create a desired frequency resonant shift. In FIG. **13**B, a fractal antenna **810** is fabricated on a first surface **820**A of a flexible substrate **820**, whose second surface **820**B does not contain an antenna or other conductor in this embodiment. Curving substrate **820**, which may be a flexible film, appears to cause electromagnetic fields associated with antenna **810** to be sufficiently in self-proximity so as to shift resonant frequencies. Such self-proximity antennas or resonators may be referred to a com-cyl devices. The extent of curvature may be controlled where a flexible substrate or substrate-less fractal antenna and/or conductive element is present, to control or tune frequency dependent characteristics of the resultant system. Com-cyl embodiments could include a concentrically or eccentrically disposed fractal antenna and conductive element. Such embodiments may include telescopic elements, whose extent of "overlap" may be telescopically adjusted by contracting or lengthening the overall configuration to tune the characteristics of the resultant system. Further, more than two elements could be provided.

In FIG. **13**C, a fractal antenna **810** is formed on the outer surface **820**A of a filled substrate **820**, which may be a ferrite core. The resultant com-cyl antenna appears to exhibit self-proximity such that desired shifts in resonant frequency are produced. The geometry of the core **820**, e.g., the extent of curvature (e.g., radius in this embodiment) relative to the size of antenna **810** may be used to determine frequency shifts.

In FIG. **14**A, an antenna or resonator system is shown in which the non-driven fractal antenna **810'** is not connected to the preferably coaxial feedline **50**. The ground shield portion of feedline **50** is coupled to the groundplane conductive element **800**, but is not otherwise connected to a system ground. of course fractal antenna **810'** could be angularly rotated relative to driven antenna **810**, it could be a different configuration than antenna **810** including having a different iteration N, and indeed could incorporate other features disclosed herein (e.g., a cut).

FIG. **14**B demonstrates that the driven antenna **810** may be coupled to the feedline **50** at any point **815'**, and not necessarily at an end point **815** as was shown in FIG. **14**A.

In the embodiment of FIG. **14**C, a second ground plane element **800'** is disposed adjacent at least a portion of the system comprising driven antenna **810**, passive antenna **810'**, and the underlying conductive planar element **800**. The presence, location, geometry, and distance associated with second ground plane element **800'** from the underlying elements **810, 810', 800** permit tuning characteristics of the overall antenna or resonator system. In the multi-element sandwich-like configuration shown, the ground shield of conductor **50** is connected to a system ground but not to either ground plane **800** or **800'**. Of course more than three elements could be used to form a tunable system according to the present invention.

FIG. **14**D shows a single fractal antenna spaced apart from an underlying ground plane **800** a distance Δ, in which a region of antenna **800** is cutaway to increase resonance. In FIG. **14**D, for example, L1 denotes a cutline, denoting that portions of antenna **810** above (in the Figure drawn) L1 are cutaway and removed. So doing will increase the frequencies of resonance associated with the remaining antenna or resonator system. On the other hand, if portions of antenna **810** above cutline L2 are cutaway and removed, still higher resonances will result. Selectively cutting or etching away portions of antenna **810** permit tuning characteristics of the remaining system.

As noted, fractal elements similar to what is generically depicted in FIGS. **14**A–**14**D may be used to form a fractal vertical element in a fractal vertical antenna system, such as was described with respect to FIG. **7**D-**3**.

FIG. **15** depicts an embodiment somewhat similar to what has been described with respect to FIG. **8**B or FIG. **8**C. Once again unit **500** is a handheld transceiver, and includes fractal antennas **510**A, **510**B–**510**B', **510**C. It is again understood that a vertical antenna such as elements **193** and fractal counterpoise **510**D (shown in FIG. **8**B) may be provided. Antennas **510**B–**510**B' are similar to what has been described with respect to FIGS. **12**A–**12**B. Antennas **510**B–**510**B' are fractal antennas, not necessarily MI-2 configuration as shown, and are spaced-apart a distance Δ and, in FIG. **13**, are rotationally displaced. Collectively, the spaced-apart distance and relative rotational displacement permits tuning the characteristics of the driven antenna, here antenna **510**B. In FIG. **14**, antenna **510**A is drawn with phantom lines to better distinguish it from spaced-apart antenna **510**B. Of course passive conductor **510**B' could instead be a solid conductor such as described with respect to FIG. **11**A. Such conductor may be implemented by spraying the inner surface of the housing for unit **500** adjacent antenna **510**B with conductive paint.

In FIG. **15**, antenna **510**C is similar to what has been described with respect to FIG. **13**A, in that a cut **830** is made in the antenna, for tuning purposes. Although antenna **510**A is shown similar to what was shown in FIG. **8**B, antenna **510**A could, if desired, be formed on a curved substrate similar to FIGS. **13**B or **13**C. While FIG. **15** shows at least two different techniques for tuning antennas according to the present invention, it will be understood that a common technique could instead be used. By that it is meant that any or all of antennas **510**A, **510**B–**510**B', **510**C could include a cut, or be spaced-apart a controllable distance Δ, or be rotatable relative to a spaced-apart conductor.

As described with respect to FIG. **8**B, an electronic circuit **610** may be coupled by cables **50**A, **50**B, **50**C to the antennas, and samples incoming signals to discern which fractal antenna, e.g., **510**A, **510**B–**510**B', **510**C (and, if present, antenna **510**D-**197**) is presently most optimally aligned with the transmitting station, perhaps a unit **600** or **650** or **660** as shown in FIG. **8**A. This determination may be made by examining signal strength from each of the antennas. An electronic circuit **620** then selects the presently best oriented antenna, and couples such antenna to the input of the receiver and output of the transmitter portion, collectively **630**, of unit **500**. It is understood that the selection of the best antenna is dynamic and can change as, for example, a user of **500** perhaps walks about holding the unit, or the transmitting source moves, or due to other changing conditions. In a cellular or a wireless telephone application, the result is more reliable communication, with the advantage that the fractal antennas can be sufficiently small-sized as to fit totally within the casing of unit **500**. Further, if a flexible substrate is used, the antennas may be wrapped about portions of the internal casing, as shown.

An additional advantage of the embodiment of FIG. **8**B is that the user of unit **500** may be physically distanced from the antennas by a greater distance that if a conventional external whip antenna were used. Although medical evidence attempting to link cancer with exposure to electromagnetic radiation from handheld transceivers is still inconclusive, the embodiment of FIG. **8**B appears to minimize any such risk.

Modifications and variations may be made to the disclosed embodiments without departing from the subject and spirit of the invention as defined by the following claims. While common fractal families include Koch, Minkowski, Julia, diffusion limited aggregates, fractal trees, Mandelbrot, ground counterpoise elements and/or top-hat loading elements according to the present invention may be implemented with other fractals as well.

What is claimed is:

1. An antenna system including:

a driven element, and

a fractal counterpoise element having a portion that includes at least a first motif and a first replication of said first motif and a second replication of said first motif such that a point chosen on a geometric figure represented by said first motif will result in a corresponding point on said first replication and on said second replication of said first motif; wherein there exists at least one non-straight line locus connecting each said point;

wherein a replication of said first motif is a change selected from a group consisting of (a) a rotation and change of scale of said first motif, (b) a linear displacement translation and a change of scale of said first motif, and (c) a rotation and a linear displacement translation and a change of scale of said first motif; and

wherein said fractal counterpoise element has a perimeter compression parameter (PC) defined by:

PC=(full-sized antenna element length)/(fractal-reduced antenna element length)

in which PC=A·log(N(D+C)). A and C are constant coefficients for said first motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional fractal counterpoise element lengths before and after fractalization, respectively.

2. The antenna system of claim **1**, wherein said first motif is selected from a group consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

3. The antenna system of claim **1**, wherein said driven element includes an element having a portion that includes at least a second motif and a first replication of said second motif and a second replication of said second motif such that a point chosen on a geometric figure represented by said second motif will result in a corresponding point on said first replication and on said second replication of said second motif; wherein there exists at least one non-straight line locus connecting each said point; and wherein a replication of said second motif is a change selected from a group consisting of (a) a rotation and change of scale of said second motif, (b) a linear displacement translation and a change of scale of said second motif, and (c) a rotation and a linear displacement translation and a change of scale of said second motif.

4. The antenna system of claim **1**, wherein said driven element includes a spaced-apart second element having a portion that includes at least a third motif and a first replication of said third motif and a second replication of said third motif such that a point chosen on a geometric figure represented by said third motif will result in a corresponding point on said first replication and on said second replication of said third motif; wherein there exists at least one non-straight line locus connecting each said point; and

wherein a replication of said third motif is a change selected from a group consisting of (a) a rotation and change of scale of said third motif, (b) a linear displacement translation and a change of scale of said third motif, and (c) a rotation and a linear displacement translation and a change of scale of said third motif.

5. The antenna system of claim **3**, wherein at least one of said first motif and said second motif is selected from a group consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

6. The antenna system of claim **1**, wherein said first motif has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, y_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates for iteration N, and where f(x,y) and g(x,y) are functions defining said first motif.

7. The antenna system of claim **4**, wherein at least one of said first motif and said third motif is selected from a group consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

8. The antenna system of claim **1**, in which said fractal counterpoise element is fabricated in a manner selected from a group consisting of (i) shaping conductive wire to form said fractal counterpoise element, (ii) forming upon an insulator substrate a conductive layer defining traces shaped to form said fractal counterpoise element, (iii) forming upon a flexible insulator substrate conductive traces shaped to form said fractal counterpoise element, and (iv) forming upon a semiconductor substrate a layer of conductive material shaped to form said fractal counterpoise element.

9. The antenna system of claim **1**, wherein:

said antenna system is a vertical antenna system;

said fractal counterpoise element includes three dendrite elements that each have an overall length approximating 0.087 λ where λ is wavelength at a resonant frequency of interest; and wherein gain of said antenna system is within at least 1 dB of unity.

10. A fractal antenna coupleable to a transceiver unit, the fractal antenna comprising:

a driven element, and

a ground counterpoise system including at least one fractal counterpoise element having a portion that includes at least a first motif and a first replication of said first motif and a second replication of said first motif such that a point chosen on a geometric figure represented by said first motif will result in a corresponding point on said first replication and on said second replication of said first motif; wherein there exists at least one non-straight line locus connecting each said point;

wherein a replication of said first motif is a change selected from a group consisting of (a) a rotation and change of scale of said first motif, (b) a linear displacement translation and a change of scale of said first motif, and (c) a rotation and a linear displacement translation and a change of scale of said first motif; and

wherein said first motif is selected from a group consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

11. The fractal antenna of claim **10**, wherein said fractal counterpoise element is fabricated in a manner selected from a group consisting of (i) shaping conductive wire to form said fractal counterpoise element, (ii) forming upon an insulator substrate a conductive layer defining traces shaped to form said fractal counterpoise element, (iii) forming upon a flexible insulator substrate conductive traces shaped to form said fractal counterpoise element, and (iv) forming upon a semiconductor substrate a layer of conductive material shaped to form said fractal counterpoise element.

12. The fractal antenna of claim **10**, wherein said first motif has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, y_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates for iteration N, and where f(x,y) and g(x,y) are functions defining said first motif.

13. The fractal antenna of claim **10**, wherein said ground counterpoise system has a perimeter compression parameter (PC) defined by:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC = A \cdot \log[N(D+C)]$$

in which A and C are constant coefficients for said first motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional fractal counterpoise system lengths before and after fractalization, respectively.

14. The fractal antenna of claim **10**, wherein:

said transceiver unit is hand holdable in size;

said antenna is mounted within a housing of said transceiver unit; and

said fractal counterpoise element is fabricated in a manner selected from a group consisting of (i) shaping conductive wire to form said fractal counterpoise element, (ii) forming upon an insulator substrate a conductive layer defining traces shaped to form said fractal counterpoise element, (iii) forming upon a flexible insulator substrate conductive traces shaped to form said fractal counterpoise element, and (iv) forming upon a semiconductor substrate a layer of conductive material shaped to form said fractal counterpoise element.

15. The fractal antenna of claim **10**, wherein said transceiver includes a plurality of such fractal antennas arrayed in at least one configuration selected from a group consisting of (i) an array of substantially identical said fractal antennas coupled to an electronic circuit that dynamically selects a chosen one of said fractal antennas to be electronically coupled to said transceiver unit, (ii) an array of substantially identical such fractal antennas coupled to an electronic circuit that dynamically selects a chosen one of said fractal antennas to be electronically coupled to said transceiver unit wherein at least two fractal antennas in said array differ in antenna orientation from other fractal antennas in said array, (iii) a plurality of said fractal antennas wherein at least two said fractal antennas have elements that differ from elements in other said fractal antennas.

16. The antenna of claim **10**, wherein said driven element has a portion that includes at least a second motif provided by a fractal generator, and a conductive element spaced-apart from said driven element by a distance Δ chosen to vary at least one characteristic of said antenna, at a desired frequency c/λ where λ and wavelength at a frequency of interest and c is velocity of light, selected from the group consisting of (i) resonant frequency, and (ii) bandwidth.

17. The antenna of claim **16**, wherein said antenna is tunable by varying at least one parameter selected from a group consisting of (a) said distance Δ, (b) relative rotation between at least a part of said ground counterpoise system and said portion of said driven element, (c) location at which a feedline center lead is coupled to said portion of said driven element, (d) location of a cut in said portion of said driven element, and (e) size of a cut-away region of said portion of said driven element.

18. A top-hat loaded antenna, comprising:

a vertical element having an upper end and a lower end; and

a top-hat assembly electrically coupled to said upper end of said vertical element;

wherein said top-hat assembly includes a top-hat element having a portion that includes a first motif and a first replication of said first motif and a second replication of said first motif such that a point chosen on a geometric figure represented by said first motif will result in a corresponding point on said first replication and on said second replication of said first motif; wherein there exists at least one non-straight line locus connecting each said point;

wherein a replication of said first motif is a change selected from a group consisting of (a) a rotation and change of scale of said first motif, (b) a linear displacement translation and a change of scale of said first motif, and (c) a rotation and a linear displacement translation and a change of scale of said first motif; and

wherein said top-hat element has a perimeter compression parameter (PC) defined by:

PC=(full-sized antenna element length)/(fractal-reduced antenna element length)

in which PC=A·log(N(D+C)), A and C are constant coefficients for said first motif, N is an iteration number, and D is a fractal dimension given by log(L)/log(r), where L and r are one-dimensional fractal top-hat element lengths before and after fractalization, respectively.

19. The antenna of claim **18**, wherein said first motif is selected from a group consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

(57) **ABSTRACT**

An antenna system includes a fractalized element that may be a ground counterpoise, a top-hat located load assembly, or a microstrip patch antenna having at least one element whose physical shape is at least partially defined as a first or higher iteration deterministic fractal. The resultant fractal element may rely upon an opening angle for performance, and is more compact than non-Euclidean ground counterpoise elements or the like. A vertical antenna system includes a vertical element that may also be a fractal, and a vertical antenna can include vertically spaced-apart fractal conductive and passive elements, and at least one fractal ground element. Various antenna configurations may be fabricated on opposite surfaces of a substrate, including a flexible substrate, and may be tuned by rotating elements relative to each other, and/or by varying the spaced-apart distance therebetween. Fractalized ground counterpoise elements and/or microstrip patch antenna systems may be fabricated on a flexible printed circuit substrate, and/or placed within the support mount of a cellular telephone car antenna.

FRACTAL ANTENNA GROUND COUNTERPOISE, GROUND PLANES, AND LOADING ELEMENTS AND MICROSTRIP PATCH ANTENNAS WITH FRACTAL STRUCTURE

RELATION TO PREVIOUSLY FILED PATENT APPLICATIONS

This application is a continuing application from applicant's co-pending patent application Ser. No. 09/677,645 entitled Fractal Antenna Ground Counterpoise, Ground Planes, And Loading Elements And Microstrip Patch Antennas With Fractal Structure, filed 3 Oct. 2000, which in turn is a continuing application of application Ser. No. 08/967, 375 entitled Fractal Antenna Ground Counterpoise, Ground Planes, And Loading Elements, filed 7 Nov. 1997, and from applicant's patent application Ser. No. 08/965,914 entitled Microstrip Patch Antennas With Fractal Structure, filed 7 Nov. 1997, issued as U.S. Pat. No. 6,127,977 (3 Oct. 2000). Applicant incorporate by reference herein his U.S. Pat. No. 6,104,349 (15 Aug. 2000) entitled Tuning Fractal Antennas and Fractal Resonators.

FIELD OF THE INVENTION

The present invention relates to antennas and resonators, and microstrip patch antennas, and specifically to designing and tuning non-Euclidian antenna ground radials, ground counterpoise or planes, top-loading elements, and antennas using such elements and to providing microstrip patch antennas with fractal structure elements.

BACKGROUND OF THE INVENTION

Antenna are used to radiate and/or receive typically electromagnetic signals, preferably with antenna gain, directivity, and efficiency. Practical antenna design traditionally involves trade-offs between various parameters, including antenna gain, size, efficiency, and bandwidth.

Antenna design has historically been dominated by Euclidean geometry. In such designs, the closed antenna area is directly proportional to the antenna perimeter. For example, if one doubles the length of an Euclidean square (or "quad") antenna, the enclosed area of the antenna quadruples. Classical antenna design has dealt with planes, circles, triangles, squares, ellipses, rectangles, hemispheres, paraboloids, and the like, (as well as lines). Similarly, resonators, typically capacitors ("C") coupled in series and/or parallel with inductors ("L"), traditionally are implemented with Euclidian inductors.

With respect to antennas, prior art design philosophy has been to pick a Euclidean geometric construction, e.g., a quad, and to explore its radiation characteristics, especially with emphasis on frequency resonance and power patterns. The unfortunate result is that antenna design has far too long concentrated on the ease of antenna construction, rather than on the underlying electromagnetics.

Many prior art antennas are based upon closed-loop or island shapes. Experience has long demonstrated that small sized antennas, including loops, do not work well, one reason being that radiation resistance ("R") decreases sharply when the antenna size is shortened. A small sized loop, or even a short dipole, will exhibit a radiation pattern of ½λ and ¼λ, respectively, if the radiation resistance R is not swamped by substantially larger ohmic ("O") losses. Ohmic losses can be minimized using impedance matching networks, which can be expensive and difficult to use. But although even impedance matched small loop antennas can exhibit 50% to 85% efficiencies, their bandwidth is inherently narrow, with very high Q, e.g., Q>50. As used herein, Q is defined as (transmitted or received frequency)/(3 dB bandwidth).

As noted, it is well known experimentally that radiation resistance R drops rapidly with small area Euclidean antennas. However, the theoretical basis is not generally known, and any present understanding (or misunderstanding) appears to stem from research by J. Kraus, noted in *Antennas* (Ed. 1), McGraw Hill, New York (1950), in which a circular loop antenna with uniform current was examined. Kraus' loop exhibited a gain with a surprising limit of 1.8 dB over an isotropic radiator as loop area fells below that of a loop having a 1λ-squared aperture. For small loops of area $A<\lambda^2/100$, radiation resistance R was given by:

$$R = K\cdot\left(\frac{A}{\lambda^2}\right)^2$$

where K is a constant, A is the enclosed area of the loop, and λ is wavelength. Unfortunately, radiation resistance R can all too readily be less than 1Ω for a small loop antenna.

From his circular loop research Kraus generalized that calculations could be defined by antenna area rather than antenna perimeter, and that his analysis should be correct for small loops of any geometric shape. Kraus' early research and conclusions that small-sized antennas will exhibit a relatively large ohmic resistance O and a relatively small radiation resistance R, such that resultant low efficiency defeats the use of the small antenna have been widely accepted. In fact, some researchers have actually proposed reducing ohmic resistance O to 0Ω by constructing small antennas from superconducting material, to promote efficiency.

As noted, prior art antenna and resonator design has traditionally concentrated on geometry that is Euclidean. However, one non-Euclidian geometry is fractal geometry. Fractal geometry may be grouped into random fractals, which are also termed chaotic or Brownian fractals and include a random noise components, such as depicted in FIG. **3**, or deterministic fractals such as shown in FIG. **1**C.

In deterministic fractal geometry, a self-similar structure results from the repetition of a design or motif (or "generator"), on a series of different size scales. One well known treatise in this field is *Fractals, Endlessly Repeated Geometrical Figures,* by Hans Lauwerier, Princeton University Press (1991), which treatise applicant refers to and incorporates herein by reference.

FIGS. **1**A–**2**D depict the development of some elementary forms of fractals. In FIG. **1**A, a base element **10** is shown as a straight line, although a curve could instead be used. In FIG. **1**B, a so-called Koch fractal motif or generator **20-1**, here a triangle, is inserted into base element **10**, to form a first order iteration ("N") design, e.g., N=1. In FIG. **1**C, a second order N=2 iteration design results from replicating the triangle motif **20-1** into each segment of FIG. **1**B, but where the **20-1'** version has been differently scaled, here reduced in size. As noted in the Lauwerier treatise, in its replication, the motif may be rotated, translated, scaled in dimension, or a combination of any of these characteristics. Thus, as used herein, second order of iteration or N=2 means the fundamental motif has been replicated, after rotation, translation, scaling (or a combination of each) into the first order iteration pattern. A higher order, e.g., N=3, iteration means a third fractal pattern has been generated by including yet another rotation; translation, and/or scaling of the first order motif.

In FIG. **1**D, a portion of FIG. **1**C has been subjected to a further iteration (N=3) in which scaled-down versions of the triangle motif **20-1** have been inserted into each segment of the left half of FIG. **1**C. FIGS. **2**A–2C follow what has been described with respect to FIGS. **1**A–1C, except that a rectangular motif **20-2** has been adopted. FIG. **2**D shows a pattern in which a portion of the left-hand side is an N=3 iteration of the **20-2** rectangle motif, and in which the center portion of the figure now includes another motif, here a **20-1** type triangle motif, and in which the right-hand side of the figure remains an N=2 iteration.

Traditionally, non-Euclidean designs including random fractals have been understood to exhibit antiresonance characteristics with mechanical vibrations. It is known in the art to attempt to use non-Euclidean random designs at lower frequency regimes to absorb, or at least not reflect sound due to the antiresonance characteristics. For example, M. Schroeder in *Fractals, Chaos. Power Laws* (1992), W. H. Freeman, New York discloses the use of presumably random or chaotic fractals in designing sound blocking diffusers for recording studios and auditoriums.

Experimentation with non-Euclidean structures has also been undertaken with respect to electromagnetic waves, including radio antennas. In one experiment, Y. Kim and D. Jaggard in *The Fractal Random Array*, Proc. IEEE 74, 1278–1280 (1986) spread-out antenna elements in a sparse microwave array, to minimize sidelobe energy without having to use an excessive number of elements. But Kim and Jaggard did not apply a fractal condition to the antenna elements, and test results were not necessarily better than any other techniques, including a totally random spreading of antenna elements. More significantly, the resultant array was not smaller than a conventional Euclidean design.

Prior art spiral antennas, cone antennas, and V-shaped antennas may be considered as a continuous, deterministic first order fractal, whose motif continuously expands as distance increases from a central point. A log-periodic antenna may be considered a type of continuous fractal in that it is fabricated from a radially expanding structure. However, log periodic antennas do not utilize the antenna perimeter for radiation, but instead rely upon an arc-like opening angle in the antenna geometry. Such opening angle is an angle that defines the size-scale of the log-periodic structure, which structure is proportional to the distance from the antenna center multiplied by the opening angle. Further, known log-periodic antennas are not necessarily smaller than conventional driven element-parasitic element antenna designs of similar gain.

Unintentionally, first order fractals have been used to distort the shape of dipole and vertical antennas to increase gain, the shapes being defined as a Brownian-type of chaotic fractals. See F. Landstorfer and R. Sacher, *Optimisation of Wire Antennas,* J. Wiley, New York (1985). FIG. **3** depicts three bent-vertical antennas developed by Landstorfer and Sacher through trial and error, the plots showing the actual vertical antennas as a function of x-axis and y-axis coordinates that are a function of wavelength. The “EF” and “BF” nomenclature in FIG. **3** refer respectively to end-fire and back-fire radiation patterns of the resultant bent-vertical antennas.

First order fractals have also been used to reduce horn-type antenna geometry, in which a double-ridge horn configuration is used to decrease resonant frequency. See J. Kraus in *Antennas,* McGraw Hill, New York (1885). The use of rectangular, box-like, and triangular shapes as impedance-matching loading elements to shorten antenna element dimensions is also known in the art.

Whether intentional or not, such prior art attempts to use a quasi-fractal or fractal motif in an antenna employ at best a first order iteration fractal. By first iteration it is meant that one Euclidian structure is loaded with another Euclidean structure in a repetitive fashion, using the same size for repetition. FIG. **1**C, for example, is not first order because the **20-1'** triangles have been shrunk with respect to the size of the first motif **20-1**.

So-called microstrip patch antennas have traditionally been fabricated as two spaced-apart metal surfaces separated by a small width dielectric. The sides are dimensioned typically one-quarter wavelength or one-half wavelength at the frequency of interest. One surface is typically a simple Euclidean structure such as a circle, a square, while the other side is a ground plane. Attempting to reduce the physical size of such an antenna for a given frequency typically results in a poor feedpoint match (e.g., to coaxial or other feed cable), poor radiation bandwidth, among other difficulties.

Prior art antenna design does not attempt to exploit multiple scale self-similarity of real fractals. This is hardly surprising in view of the accepted conventional wisdom that because such antennas would be anti-resonators, and/or if suitably shrunken would exhibit so small a radiation resistance R, that the substantially higher ohmic losses **0** would result in too low an antenna efficiency for any practical use. Further, it is probably not possible to mathematically predict such an antenna design, and high order iteration fractal antennas would be increasingly difficult to fabricate and erect, in practice. The use of fractals, especially higher order fractals, in fabricating microstrip patch antennas has not been investigated in the prior art.

FIGS. **4**A and **4**B depict respective prior art series and parallel type resonator configurations, comprising capacitors C and Euclidean inductors L. In the series configuration of FIG. **4**A, a notch-filter characteristic is presented in that the impedance from port A to port B is high except at frequencies approaching resonance, determined by $1/\sqrt{(LC)}$.

In the distributed parallel configuration of FIG. **4**B, a low-pass filter characteristic is created in that at frequencies below resonance, there is a relatively low impedance path from port A to port B, but at frequencies greater than resonant frequency, signals at port A are shunted to ground (e.g., common terminals of capacitors C), and a high impedance path is presented between port A and port B. Of course, a single parallel LC configuration may also be created by removing (e.g., short-circuiting) the rightmost inductor L and right two capacitors C, in which case port B would be located at the bottom end of the leftmost capacitor C.

In FIGS. **4**A and **4**B, inductors L are Euclidean in that increasing the effective area captured by the inductors increases with increasing geometry of the inductors, e.g., more or larger inductive windings or, if not cylindrical, traces comprising inductance. In such prior art configurations as FIGS. **4**A and **4**B, the presence of Euclidean inductors L ensures a predictable relationship between L, C and frequencies of resonance.

Applicant’s cited applications provide design methodologies to produce smaller-scale antennas that can exhibit at least as much gain, directivity, and efficiency as larger Euclidean counterparts. Such design approach should exploit the multiple scale self-similarity of real fractals, including $N \geqq 2$ iteration order fractals. Further, said application disclosed a non-Euclidean resonator whose presence in a resonating configuration can create frequencies of resonance beyond those normally presented in series and/or parallel LC configurations. Applicant's above-noted TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS patent disclosed devices and methods for tuning and/or adjusting such antennas and resonators. This patent further disclosed the use of non-Euclidean resonators whose presence in a resonating configuration could create frequencies of resonance beyond those normally presented in series and/or parallel LC configurations.

However, such antenna design approaches and tuning approaches should also be useable with vertical antennas, permitting the downscaling of one or more radial ground plane elements, and/or ground planes, and/or ground counterpoises, and/or top-hat loading elements. Further, such antenna design approaches and tuning approaches should also be useable with microstrip patch antennas and elements for such antennas. Thus, there is a need for a method by which microstrip patch antennas could be made smaller without sacrificing antenna bandwidth, while preserving good feedpoint impedance matching, and while maintaining acceptable gain and frequency characteristics.

The present invention provides such antennas, radial ground plane elements, ground planes, ground counterpoises, and top-hat loading elements, as well as methods for their design, and further provides such microstrip patch antennas, and elements for such antennas.

SUMMARY OF THE INVENTION

In one aspect, the present invention provides an antenna with a ground plane or ground counterpoise system that has at least one element whose shape, at least is part, is substantially a deterministic fractal of iteration order $N \geqq 1$. (The term "ground counterpoise" will be understood to include a ground plane, and/or at least one ground element.) Using fractal geometry, the antenna ground counterpoise has a self-similar structure resulting from the repetition of a design or motif (or "generator") that is replicated using rotation, and/or translation, and/or scaling. The fractal element will have x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, yb_N)$ and $y_{N+1}=g(x_N, y_N$, where x_N, y_N define coordinates for a preceding iteration, and where f(x,y) and g(x,y) are functions defining the fractal motif and behavior. In another aspect, a vertical antenna is top-loaded with a so-called top-hat assembly that includes at least one fractal element. A fractalized top-hat, assembly advantageously reduces resonant frequency, as well as the physical size and area required for the top-hat assembly.

In contrast to Euclidean geometric antenna design, deterministic fractal elements according to the present invention have a perimeter that is not directly proportional to area. For a given perimeter dimension, the enclosed area of a multi-iteration fractal will always be as small or smaller than the area of a corresponding conventional Euclidean element.

A fractal antenna has a fractal ratio limit dimension D given by log(L)/log(r), where L and r are one-dimensional antenna element lengths before and after fractalization, respectively.

As used herein, a fractal antenna perimeter compression parameter (PC) is defined as:

$$PC = \frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

where:

$$PC = A \cdot \log[N(D+C)]$$

in which A and C are constant coefficients for a given fractal motif, N is an iteration number, and D is the fractal dimension, defined above.

Radiation resistance (R) of a fractal antenna decreases as a small power of the perimeter compression (PC), with a fractal loop or island always exhibiting a substantially higher radiation resistance than a small Euclidean loop antenna of equal size. In the present invention, deterministic fractals are used wherein A and C have large values, and thus provide the greatest and most rapid element-size shrinkage. A fractal antenna according to the present invention will exhibit an increased effective wavelength.

The number of resonant nodes of a fractal loop-shaped antenna increases as the iteration number N and is at least as large as the number of resonant nodes of an Euclidean island with the same area. Further, resonant frequencies of a fractal antenna include frequencies that are not harmonically related.

An antenna including a fractal ground counterpoise according to the present invention is smaller than its Euclidean counterpart but provides at least as much gain and frequencies of resonance and provides a reasonable termination impedance at its lowest resonant frequency. Such an antenna system can exhibit non-harmonically frequencies of resonance, a low Q and resultant good bandwidth, acceptable standing wave ratio ("SWR"), and a radiation impedance that is frequency dependent, and high efficiencies.

With respect to vertical antennas, the present invention enables such antennas to be realized with a smaller vertical element, and/or with smaller ground counterpoise, e.g., ground plane radial elements, and/or ground plane. The ground counterpoise element(s) are fractalized with $N \geqq 1$. In a preferred embodiment, the vertical element is also a fractal system, preferably comprising first and second spaced-apart fractal elements.

A fractal antenna system having a fractal ground counterpoise and a fractal vertical preferably is tuned according to applicant's above-referenced TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS patent, by placing an active (or driven) fractal antenna or resonator a distance Δ from a second conductor. Such disposition of the antenna and second conductor advantageously lowers resonant frequencies and widens bandwidth for the fractal antenna. In some embodiments, the fractal antenna and second conductor are non-coplanar and λ is the separation distance therebetween, preferably $\leqq 0.05\lambda$ for the frequency of interest ($1/\lambda$). In other embodiments, the fractal antenna and second conductive element may be planar, in which case λ a separation distance, measured on the common plane. In another embodiment, an antenna is loaded with a fractal "top-hat" assembly, which can provide substantial reduction in antenna size.

The second conductor may in fact be a second fractal antenna of like or unlike configuration as the active antenna.

Varying the distance Δ tunes the active antenna and thus the overall system. Further, if the second element, preferably a fractal antenna, is angularly rotated relative to the active antenna, resonant frequencies of the active antenna may be varied.

Providing a cut in the fractal antenna results in new and different resonant nodes, including resonant nodes having perimeter compression parameters, defined below, ranging from about three to ten. If desired, a portion of a fractal antenna may be cutaway and removed so as to tune the antenna by increasing resonance(s).

Tunable antenna systems with a fractal ground counterpoise need not be planar, according to the present invention. Fabricating the antenna system around a form such as a toroid ring, or forming the fractal antenna on a flexible substrate that is curved about itself results in field self-proximity that produces resonant frequency shifts. A fractal antenna and a conductive element may each be formed as a curved surface or even as a toroid-shape, and placed in sufficiently close proximity to each other to provide a useful tuning and system characteristic altering mechanism.

In the various embodiments, more than two elements may be used, and tuning may be accomplished by varying one or more of the parameters associated with one or more elements.

In a second aspect, the present invention provides a microstrip patch antenna comprising spaced-apart first and second conductive surfaces separated by a dielectric material. The dielectric material thickness preferably is substantially less than one wavelength for the frequency of interest.

At least one of the surfaces is fabricated to define a fractal pattern of first or higher iteration order. Overall dimensions of the surfaces may be reduced below the one-quarter to one-half wavelength commonly found in the prior art.

Radio frequency feedline coupling to the microstrip patch antenna may be made at a location on the antenna pattern structure, or through a conductive feedtab strip that may be fabricated along with the conductive pattern on one or both surfaces of the antenna. The resultant antenna may be sized smaller than a non-fractal counterpart (e.g., approximately one-eighth wavelength provides good performance at about 900 MHz.) while preserving good, preferably 50Ω, feed-point impedance. Further bandwidth can actually be increased, and resonant frequency lowered.

Components from the generally-described first and second aspects of the present invention may be combined.

Other features and advantages of the invention will appear from the following description in which the preferred embodiments have been set forth in detail, in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1**A depicts a base element for an antenna or an inductor, according to the prior art;

FIG. **1**B depicts a triangular-shaped Koch fractal motif, according to the prior art;

FIG. **1**C depicts a second-iteration fractal using the motif of FIG. **1**B, according to the prior art;

FIG. **1**D depicts a third-iteration fractal using the motif of FIG. **1**B, according to the prior art;

FIG. **2**A depicts a base element for an antenna or an inductor, according to the prior art;

FIG. **2**B depicts a rectangular-shaped Minkowski fractal motif, according to the prior art;

FIG. **2**C depicts a second-iteration fractal using the motif of FIG. **2**B, according to the prior art;

FIG. **2**D depicts a fractal configuration including a third-order using the motif of FIG. **2**B, as well as the motif of FIG. **1**B, according to the prior art;

FIG. **3** depicts bent-vertical chaotic fractal antennas, according to the prior art;

FIG. **4**A depicts a series L-C resonator, according to the prior art;

FIG. **4**B depicts a distributed parallel L-C resonator, according to the prior art;

FIG. **5**A depicts an Euclidean quad antenna system, according to the prior art;

FIG. **5**B depicts a second-order Minkowski island fractal quad antenna, according to the present invention;

FIG. **6** depicts an ELNEC-generated free-space radiation pattern for an MI-2 fractal antenna, according to the present invention;

FIG. **7**A depicts a Cantor-comb fractal dipole antenna, according to the present invention;

FIG. **7**B depicts a torn square fractal quad antenna, according to the present invention;

FIG. **7**C-**1** depicts a second iteration Minkowski (MI-2) printed circuit fractal antenna, according to the present invention;

FIG. **7**C-**2** depicts a second iteration Minkowski (MI-2) slot fractal antenna, according to the present invention;

FIG. **7**D depicts a deterministic dendrite fractal vertical antenna, according to the present invention;

FIG. **7**D-**1**A depicts a 0.25λ vertical antenna with three 0.25λ radial ground elements, according to the prior art;

FIG. **7**D-**1**B depicts the gain pattern for the antenna of FIG. **7**D-**1**A;

FIG. **7**D-**2**A depicts a 0.25λ vertical antenna with three fractal radial ground elements according to the present invention;

FIG. **7**D-**2**B depicts the gain pattern for the antenna of FIG. **7**D-**2**A;

FIG. **7**D-**3**A depicts a "top-hat" loaded antenna, according to the prior art;

FIG. **7**D-**3**B depicts the gain pattern for the antenna of FIG. **7**D-**3**A;

FIG. **7**D-**4**A depicts a ternary fractal "top-hat" loaded antenna, according the present invention;

FIG. **7**D-**4**B depicts the gain pattern for the antenna of FIG. **7**D-**4**A;

FIG. **7**D-**5** depicts an antenna having a fractal vertical element and fractal radial ground elements, according to the present invention;

FIG. **7**E depicts a third iteration Minkowski island (MI-3) fractal quad antenna, according to the present invention;

FIG. **7**F depicts a second iteration Koch fractal dipole, according to the present invention;

FIG. **7**G depicts a third iteration dipole, according to the present invention;

FIG. **7**H depicts a second iteration Minkowski fractal dipole, according to the present invention;

FIG. **7**I depicts a third iteration multi-fractal dipole, according to the present invention;

FIG. **8**A depicts a generic system in which a passive or active -electronic system communicates using a fractal antenna, according to the present invention;

FIG. **8**B depicts a communication system in which several fractal antennas including a vertical antenna with a fractal ground counterpoise are electronically selected for best performance, according to the present invention;

FIG. **8**C depicts a communication system in which electronically steerable arrays of fractal antennas are electronically selected for best performance, according to the present invention;

FIG. **9**A depicts fractal antenna gain as a function of iteration order N, according to the present invention;

FIG. **9**B depicts perimeter compression PC as a function of iteration order N for fractal antennas, according to the present invention;

FIG. **10**A depicts a fractal inductor for use in a fractal resonator, according to the present invention;

FIG. **10**B depicts a credit card sized security device utilizing a fractal resonator, according to the present invention;

FIG. **11**A depicts an embodiment in which a fractal antenna is spaced-apart a distance Δ from a conductor element to vary resonant properties and radiation characteristics of the antenna, according to the present invention;

FIG. **11**B depicts an embodiment in which a fractal antenna is coplanar with a ground plane and is spaced-apart a distance Δ' from a coplanar passive parasitic element to vary resonant properties and radiation characteristics of the antenna, according to the present invention;

FIG. **12**A depicts spacing-apart first and second fractal antennas a distance Δ to decrease resonance and create additional resonant frequencies for the active or driven antenna, according to the present invention;

FIG. **12**B depicts relative angular rotation between spaced-apart first and second fractal antennas Δ to vary resonant frequencies of the active or driven antenna, according to the present invention;

FIG. **13**A depicts cutting a fractal antenna or resonator to create different resonant nodes and to alter perimeter compression, according to the present invention;

FIG. **13**B depicts forming a non-planar fractal antenna or resonator on a flexible substrate that is curved to shift resonant frequency, apparently due to self-proximity electromagnetic fields, according to the present invention;

FIG. **13**C depicts forming a fractal antenna or resonator on a curved torroidal form to shift resonant frequency, apparently due to self-proximity electromagnetic fields, according to the present invention;

FIG. **14**A depicts forming a fractal antenna or resonator in which the conductive element is not attached to the system coaxial or other feedline, according to the present invention;

FIG. **14**B depicts a system similar to FIG. **14**A, but demonstrates that the driven fractal antenna may be coupled to the system coaxial or other feedline at any point along the antenna, according to the present invention;

FIG. **14**C depicts an embodiment in which a supplemental ground plane is disposed adjacent a portion of the driven fractal antenna and conductive element, forming a sandwich-like system, according to the present invention;

FIG. **14**D depicts an embodiment in which a fractal antenna system is tuned by cutting away a portion of the driven antenna, according to the present invention;

FIG. **15** depicts a communication system similar to that of FIG. **8**A, in which several fractal antennas are tunable and are electronically selected for best performance, according to the present invention;

FIG. **16** is a sideview of a microstrip patch antenna with at least one fractal element, according to the present invention;

FIG. **17** is a top plan view of an exemplary fractal element (a Sierpinski square gasket, including an optional feedtab, according to the present invention; and

FIG. **18** is a top plan view of an exemplary alternative fractal element (a diffusion limited aggregate), including an optional feed pad, according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

In overview, in one aspect, the present invention provides an antenna system with a fractal ground counterpoise, e.g., a counterpoise and/or ground plane and/or ground element having at least one element whose shape, at least is part, is substantially a fractal of iteration order $N \geqq 1$. The resultant antenna is smaller than its Euclidean counterpart, provides close to 50Ω termination impedance, exhibits at least as much gain and more frequencies of resonance than its Euclidean counterpart, including non-harmonically related frequencies of resonance, exhibits a low Q and resultant good bandwidth, acceptable SWR, a radiation impedance that is frequency dependent, and high efficiencies.

In another aspect, the present invention provides a microstrip patch antenna with at least one element whose shape, at least is part, is substantially a fractal of iteration order $N \geqq 1$. The resultant antenna is smaller than its Euclidean counterpart, provides close to 50Ω termination impedance, exhibits acceptable gain, increased bandwidth, and decreased resonant frequency than its Euclidean counterpart.

In contrast to Euclidean geometric antenna design, a fractal element including a fractal antenna ground counterpoise according to the present invention has a perimeter that is not directly proportional to area. For a given perimeter dimension, the enclosed area of a multi-iteration fractal area will always be at least as small as any Euclidean area.

Using fractal geometry, the ground element has a self-similar structure resulting from the repetition of a design or motif (or "generator"), which motif is replicated using rotation, translation, and/or scaling (or any combination thereof). The fractal portion of the element has x-axis, y-axis coordinates for a next iteration N+1 defined by $x_{N+1}=f(x_N, yb_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates of a preceding iteration, and where f(x,y) and g(x,y) are functions defining the fractal motif and behavior.

For example, fractals of the Julia set may be represented by the form:

$$x_{N+1}=x_N^2-y_N^2+a$$

$$y_{N+1}=2x_N \cdot y_N=b$$

In complex notation, the above may be represented as:

$$z_{N+1}=z_N^2+c$$

Although it is apparent that fractals can comprise a wide variety of forms for functions f(x,y) and g(x,y), it is the iterative nature and the direct relation between structure or morphology on different size scales that uniquely distinguish f(x,y) and g(x,y) from non-fractal forms. Many references including the Lauwerier treatise set forth equations appropriate for f(x,y) and g(x,y).

Iteration (N) is defined as the application of a fractal motif over one size scale. Thus, the repetition of a single size scale of a motif is not a fractal as that term is used herein. Multi-fractals may of course be implemented, in which a motif is changed for different iterations, but eventually at least one motif is repeated in another iteration.

The first aspect of the present invention will now be described with reference to FIGS. **5A-15**, and then the second aspect will be described with reference to FIGS. **16–18**. As noted, elements of each aspect may be combined.

An overall appreciation of the present invention, and especially the first aspect thereof, may be obtained by comparing FIGS. **5**A and **5**B. FIG. **5**A shows a conventional Euclidean quad antenna **5** having a driven element **10** whose four sides are each 0.25λ long, for a total perimeter of 1λ, where λ is the frequency of interest.

Euclidean element **10** has an impedance of perhaps 130Ω, which impedance decreases if a parasitic quad element **20** is spaced apart on a boom **30** by a distance B of 0.1λ to 0.25λ. Parasitic element **20** is also sized S=0.25λ on a side, and its presence can improve directivity of the resultant two-element quad antenna. Element **10** is depicted in FIG. **5**A with heavier lines than element **20**, solely to avoid confusion in understanding the figure. Non-conductive spreaders **40** are used to help hold element **10** together and element **20** together.

Because of the relatively large drive impedance, driven element **10** is coupled to an impedance matching network or device **60**, whose output impedance is approximately 50Ω. A typically 50Ω coaxial cable **50** couples device **60** to a transceiver **70** or other active or passive electronic equipment **70**.

As used herein, the term transceiver shall mean a piece of electronic equipment that can transmit, receive, or transmit and receive an electromagnetic signal via an antenna, such as the quad antenna shown in FIG. **5**A or **5**B. As such, the term transceiver includes without limitation a transmitter, a receiver, a transmitter-receiver, a cellular telephone, a wireless telephone, a pager, a wireless computer local area network ("LAN") communicator, a passive resonant unit used by stores as part of an anti-theft system in which transceiver **70** contains a resonant circuit that is blown or not-blown by an electronic signal at time of purchase of the item to which transceiver **70** is affixed, resonant sensors and transponders, and the like.

Further, since antennas according to the present invention can receive incoming radiation and coupled the same as alternating current into a cable, it will be appreciated that fractal antennas may be used to intercept incoming light radiation and to provide a corresponding alternating current. For example, a photocell antenna defining a fractal, or indeed a plurality or array of fractals, would be expected to output more current in response to incoming light than would a photocell of the same overall array size.

FIG. **5**B depicts a fractal quad antenna **95**, designed to resonant at the same frequency as the larger prior art antenna **5** shown in FIG. **5**A. Driven element **100** is seen to be a second order fractal, here a so-called Minkowski island fractal, although any of numerous other fractal configurations could instead be used, including without limitation, Koch, torn square, Mandelbrot, Caley tree, monkey's swing, Sierpinski gasket, and Cantor gasket geometry.

If one were to measure to the amount of conductive wire or conductive trace comprising the perimeter of element **40**, it would be perhaps 40% greater than the 1.0λ for the Euclidean quad of FIG. **5**A. However, for fractal antenna **95**, the physical straight length of one element side KS will be substantially smaller, and for the N=2 fractal antenna shown in FIG. **5**B, KS≈0.13λ (in air), compared with K≈0.25λ for prior art antenna **5**.

However, although the actual perimeter length of element **100** is greater than the 1λ perimeter of prior art element **10**, the area within antenna element **100** is substantially less than the S^2 area of prior art element **10**. As noted, this area independence from perimeter is a characteristic of a deterministic fractal. Boom length B for antenna **95** will be slightly different from length B for prior art antenna **5** shown in FIG. **4**A. In FIG. **5**B, a parasitic element **120**, which preferably is similar to driven element **100** but need not be, may be attached to boom **130**. For ease of illustration FIG. **5**B does not depict non-conductive spreaders, such as spreaders **40** shown in FIG. **4**A, which help hold element **100** together and element **120** together. Further, for ease of understanding the figure, element **10** is drawn with heavier lines than element **120**, to avoid confusion in the portion of the figure in which elements **100** and **120** appear overlapped.

An impedance matching device **60** is advantageously unnecessary for the fractal antenna of FIG. **5**B, as the driving impedance of element **100** is about 50Ω, e.g., a perfect match for cable **50** if reflector element **120** is absent, and about 35Ω, still an acceptable impedance match for cable **50**, if element **120** is present. Antenna **95** may be fed by cable **50** essentially anywhere in element **100**, e.g., including locations X, Y, Z, among others, with no substantial change in the termination impedance. With cable **50** connected as shown, antenna **95** will exhibit horizontal polarization. If vertical polarization is desired, connection may be made as shown by cable **50'**. If desired, cables **50** and **50'** may both be present, and an electronic switching device **75** at the antenna end of these cables can short-out one of the cables. If cable **50** is shorted out at the antenna, vertical polarization results, and if instead cable **50'** is shorted out at the antenna, horizontal polarization results.

As shown by Table 3 herein, fractal quad **95** exhibits about 1.5 dB gain relative to Euclidean quad **10**. Thus, transmitting power output by transceiver **70** may be cut by perhaps 40% and yet the system of FIG. **5**B will still perform no worse than the prior art system of FIG. **5**A. Further, as shown by Table 1, the fractal antenna of FIG. **5**B exhibits more resonance frequencies than the antenna of FIG. **5**B, and also exhibits some resonant frequencies that are not harmonically related to each other. As shown by Table 3, antenna **95** has efficiency exceeding about 92% and exhibits an excellent SWR of about 1.2:1. As shown by Table 5, applicant's fractal quad antenna exhibits a relatively low value of Q. This result is surprising in view of conventional prior art wisdom to the effect that small loop antennas will exhibit high Q.

In short, that fractal quad **95** works at all is surprising in view of the prior art (mis)understanding as to the nature of radiation resistance R and ohmic losses O. Indeed, the prior art would predict that because the fractal antenna of FIG. **5**B is smaller than the conventional antenna of FIG. **5**A, efficiency would suffer due to an anticipated decrease in radiation resistance R. Further, it would have been expected that Q would be unduly high for a fractal quad antenna.

FIG. **6** is an ELNEC-generated free-space radiation pattern for a second-iteration Minkowski fractal antenna, an antenna similar to what is shown in FIG. **5**B with the parasitic element **120** omitted. The frequency of interest was 42.3 MHz, and a 1.5:1 SWR was used. In FIG. **6**, the outer ring represents 2.091 dBi, and a maximum gain of 2.091 dBi. (ELNEC is a graphics/PC version of MININEC, which is a PC version of NEC.) In practice, however, the data shown in FIG. **6** were conservative in that a gain of 4.8 dB above an isotropic reference radiator was actually obtained. The error in the gain figures associated with FIG. **6** presumably is due to roundoff and other limitations inherent in the ELNEC program. Nonetheless, FIG. **6** is believed to accurately depict the relative gain radiation pattern of a single element Minkowski (MI-2) fractal quad according to the present invention.

FIG. **7**A depicts a third iteration Cantor-comb fractal dipole antenna, according to the present invention. Generation of a Cantor-comb involves trisecting a basic shape, e.g., a rectangle, and providing a rectangle of one-third of the basic shape on the ends of the basic shape. The new smaller rectangles are then trisected, and the process repeated. FIG. **7**B is modeled after the Lauwerier treatise, and depicts a single element torn-sheet fractal quad antenna.

As described later herein, the fractal element shown in FIG. **7**B may be used as a ground counterpoise for an antenna system, for example, for a vertical antenna. In such application, the center conductor of cable **50** would be coupled to the lower end of the vertical antenna element (not shown, but which itself may be a fractal), and the ground shield of cable **50** would be coupled to the fractal element shown in FIG. **7**B. The fractal ground poise may be substantially smaller than a conventional 0.25λ ground system, without detriment to gain, coupling impedance, and vertical polarization characteristics of the antenna system.

FIG. **7**C-**1** depicts a printed circuit antenna, in which the antenna is fabricated using printed circuit or semiconductor fabrication techniques. For ease of understanding, the etched-away non-conductive portion of the printed circuit board **150** is shown cross-hatched, and the copper or other conductive traces **170** are shown without cross-hatching.

Applicant notes that while various corners of the Minkowski rectangle motif may appear to be touching in this and perhaps other figures herein, in fact no touching occurs. Further, it is understood that it suffices if an element according to the present invention is substantially a fractal. By this it is meant that a deviation of less than perhaps 10% from a perfectly drawn and implemented fractal will still provide adequate fractal-like performance, based upon actual measurements conducted by applicant.

The substrate **150** is covered by a conductive layer of material **170** that is etched away or otherwise removed in areas other than the fractal design, to expose the substrate **150**. The remaining conductive trace portion **170** defines a fractal antenna, a second iteration Minkowski slot antenna in FIG. **7**C-**1**. Substrate **150** may be a silicon wafer, a rigid or a flexible plastic-like material, perhaps Mylar™ material, or the non-conductive portion of a printed circuit board. Overlayer **170** may be deposited doped polysilicon for a semiconductor substrate **150**, or copper for a printed circuit board substrate.

If desired, the fractal structure shown in FIG. **7**C-**1** could be utilized as a fractal ground counterpoise for an antenna system, for example a vertical antenna. The fractal ground counterpoise may be fabricated using smaller dimensions than a conventional prior art system employing typically 0.25λ ground radials or elements. If the structure shown in FIG. **7**C-**1** is used as a ground counterpoise, the center lead of cable **50** would be coupled to the vertical element (not shown), and the ground shield would be coupled to the fractal structure shown.

FIG. **7**C-**2** depicts a slot antenna version of what was shown in FIG. **7**C-**2**, wherein the conductive portion **170** (shown cross-hatched in FIG. **7**C-**2**) surrounds and defines a fractal-shape of non-conductive substrate **150**. Electrical connection to the slot antenna is made with a coaxial or other cable **50**, whose inner and outer conductors make contact as shown.

In FIGS. **7**C-**1** and **7**C-**2**, the substrate or plastic-like material in such constructions can contribute a dielectric effect that may alter somewhat the performance of a fractal antenna by reducing resonant frequency, which increases perimeter compression PC.

Those skilled in the art will appreciate that by virtue of the relatively large amount of conducting material (as contrasted to a thin wire), antenna efficiency is promoted in a slot configuration. Of course a printed circuit board or substrate-type construction could be used to implement a non-slot fractal antenna, e.g, in which the fractal motif is fabricated as a conductive trace and the remainder of the conductive material is etched away or otherwise removed. Thus, in FIG. **7**C, if the cross-hatched surface now represents non-conductive material, and the non-cross hatched material represents conductive material, a printed circuit board or substrate-implemented wire-type fractal antenna results.

Printed circuit board and/or substrate-implemented fractal antennas are especially useful at frequencies of 80 MHz or higher, whereat fractal dimensions indeed become small A 2 M MI-3 fractal antenna (e.g., FIG. **7**E) will measure about 5.5" (14 cm) on a side KS, and an MI-2 fractal antenna (e.g., FIG. **5**B) will about 7" (17.5 cm) per side KS. As will be seen from FIG. **8**A, an MI-3 antenna suffers a slight loss in gain relative to an MI-2 antenna, but offers substantial size reduction.

Applicant has fabricated an MI-2 Minkowski island fractal antenna for operation in the 850–900 MHz cellular telephone band. The antenna was fabricated on a printed circuit board and measured about 1.2" (3 cm) on a side KS. The antenna was sufficiently small to fit inside applicant's cellular telephone, and performed as well as if the normal attachable “rubber-ducky” whip antenna were still attached. The antenna was found on the side to obtain desired vertical polarization, but could be fed anywhere on the element with 50Ω impedance still being inherently present. Applicant also fabricated on a printed circuit board an MI-3 Minkowski island fractal quad, whose side dimension KS was about 0.8" (2 cm), the antenna again being inserted inside the cellular telephone. The MI-3 antenna appeared to work as well as the normal whip antenna, which was not attached. Again, any slight gain loss in going from MI-2 to MI-3 (e.g., perhaps 1 dB loss relative to an MI-0 reference quad, or 3 dB los relative to an MI-2) is more than offset by the resultant shrinkage in size. At satellite telephone frequencies of 1650 MHz or so, the dimensions would be approximated halved again. FIGS. **8**A, **8**B and **8**C depict preferred embodiments for such antennas.

FIG. **7**D depicts a 2 M dendrite deterministic fractal antenna that includes a slight amount of randomness. The vertical arrays of numbers depict wavelengths relative to 0λ, at the lower end of the trunk-like element **200**. Eight radial-like elements **210** are disposed at 1.0λ, and various other elements are disposed vertically in a plane along the length of element **200**. The antenna was fabricated using 12 gauge copper wire and was found to exhibit a surprising 20 dBi gain, which is at least 10 dB better than any antenna twice the size of what is shown in FIG. **7**D. Although superficially the vertical of FIG. **7**D may appear analogous to a log-periodic antenna, a fractal vertical according to the present invention does not rely upon an opening angle, in stark contrast to prior art log periodic designs.

FIGS. **7**D-**1**A and **7**D-**1**B depict a conventional vertical antenna **5**, comprising a 0.25λ long vertical element **195**, and three 0.25λ long ground plane radials **205**. Antenna **5** is fed using coaxial cable **50** in conventional fashion, the antenna impedance being on the order of about 24Ω. Antenna efficiency may be improved by adding additional radial elements **205**, however doing so frequently requires more space than is conveniently available. In other configurations, a ground plane or counterpoise may be used without radials, e.g., earth or the metal body of an automobile in the case of a vehicular-mounted antenna. The 0° elevation angle azimuth plot of FIG. **7**D-**1**B depicts the undesirably large horizontal polarization components (the “figure eight” pattern) exhibited by this prior art vertical system, with vertical and total gain being about 1.45 dBi.

FIG. **7D-2**A depicts an antenna system **5** according to the present invention as including a vertical element **195** and a fractalized ground counterpoise system comprising, in this example, three dendrite fractal ground radials **215**. The ground radials are coupled to the ground shield on cable **50**, whereas the center lead of cable **50** is coupled to the vertical element **195**. Of course, other fractal configurations may be used instead, and a different number of ground radials may also be used.

In the azimuth plot of FIG. **7D-2**B, the elevation angle is 0°, and each fractal ground radial element is only about 0.087λ. The maximum gain, at the outermost ring in the figure, is 1.83 dBi and the input impedance is about 30Ω. Note in FIG. **7D-2**B that relatively little energy is radiated horizontally, and nearly all of the energy is radiated vertically, a desirable characteristic for a vertical antenna. It will be appreciated that the 0.087λ dimensions of fractal ground plane elements **215** are substantially physically smaller than the 0.25λ elements **205** in the prior art system of FIG. **7D-1**A. However, the radiation pattern for the system of FIG. **7D-2**A is actually better than that of the larger prior art system.

FIG. **7D-3**A depicts a so-called “top-hat” loaded vertical antenna **5**, according to the prior art. Antenna **5** includes a vertical element **195** and, in the example shown, a top-hat assembly comprising three spokes **207** located at the antenna top. The antenna is fed in conventional fashion with coaxial cable **50**. FIG. **7D-3**B depicts the radiation pattern for the conventional top-hat loaded antenna of FIG. **7D-3**A.

FIG. **7D-4**A depicts a “top-hat” antenna **5** that includes a vertical element **195** whose top is loaded by a top-hat assembly including fractalized radial spokes **215**. Antenna **5** may be fed in conventional fashion by coaxial cable **50**. For the same vertical length of element **195** as was used in FIG. **7D-3**A, the use of fractal radial spokes **215** advantageously decreases resonant frequency by 35%. In addition, the size of the “top-hat” assembly may be reduced by about 35%, and the area required for the “top-hat” assembly may be reduced by about 35%. These reductions are advantageous in that the fractalized top-hat antenna of FIG. **7D-4**A can require less material to fabricate, thus reducing manufacturing cost, weight, and wind resistance, relative to a prior art top-hat configuration. According to the present invention, it suffices if at least one of the elements in the top-hat assembly has a physical shaped defined at least in part by a fractal. Of course, more or less than three spokes may be used, and other fractal configurations may also be used, including combinations of fractal and non-fractal elements, as well as different types of fractal elements.

FIG. **7D-4**B represents the radiation pattern for the fractalized top-hat antenna of FIG. **7D-4**A. A comparison of FIGS. **7D-4**B and **7D-3**B confirms that there is no real performance penalty associated with using the fractalized configuration. Thus, the above-noted savings in cost, weight, and wind resistance are essentially penalty free.

FIG. **7D-5** depicts an antenna system according to the present invention, in which fractal ground elements **215** and a fractal vertical element **197** are both used. Fractal antenna elements **215** are preferably about 0.087λ, and element **197** is about λ/12. Fractal vertical element **197** preferably comprises a pair of spaced-apart elements such as generally described with respect to FIGS. **11**A, **12**A, **12**B, **13**B, **14**A, **14**B, and **14**C. It is to be understood, however, that the salient feature of element **197** in FIG. **7D-3** is not its specific shape, but rather that it defines a fractal, and preferably a pair of spaced-apart fractal elements. It is solely for ease of illustration that the fractal elements shown in FIGS. **7D-3**, **11**A, **12**A, **12**B, **13**B, **14**A, **14**B, **14**C, and **14**D are similarly drawn. Further, the fractal-fractal antenna system shown in FIG. **7D-3** is preferably tuned by varying the spaced-apart distance Δ, and/or by rotating the spaced-apart elements relative to one another, and/or by forming a “cut” in an element, as described hereinafter with respect to various of FIGS. **11**A, **12**A, **12**B, **13**B, **14**A, **14**B, **14**C and **14**D.

FIG. **7**E depicts a third iteration Minkowski island quad antenna (denoted herein as MI-3). The orthogonal line segments associated with the rectangular Minkowski motif make this configuration especially acceptable to numerical study using ELNEC and other numerical tools using moments for estimating power patterns, among other modeling schemes. In testing various fractal antennas, applicant formed the opinion that the right angles present in the Minkowski motif are especially suitable for electromagnetic frequencies.

With respect to the MI-3 fractal of FIG. **7**E, applicant discovered that the antenna becomes a vertical if the center led of coaxial cable **50** is connected anywhere to the fractal, but the outer coaxial braid-shield is left unconnected at the antenna end. (At the transceiver end, the outer shield is connected to ground.) Not only do fractal antenna islands perform as vertical antennas when the center conductor of cable **50** is attached to but one side of the island and the braid is left ungrounded at the antenna, but resonance frequencies for the antenna so coupled are substantially reduced. For example, a 2" (5 cm) sized MI-3 fractal antenna resonated at 70 MHz when so coupled, which is equivalent to a perimeter compression PC≈20.

FIG. **7**F depicts a second iteration Koch fractal dipole, and FIG. **7**G a third iteration dipole. FIG. **7**H depicts a second iteration Minkowski fractal dipole, and FIG. **71** a third iteration multi-fractal dipole. Depending upon the frequencies of interest, these antennas may be fabricated by bending wire, or by etching or otherwise forming traces on a substrate. Each of these dipoles provides substantially 50Ω termination impedance to which coaxial cable **50** may be directly coupled without any impedance matching device. It is understood in these figures that the center conductor of cable **50** is attached to one side of the fractal dipole, and the braid outer shield to the other side.

A fractal ground counterpoise may be fabricated using fractal element as shown in any (or all) of FIGS. **7**E-**7**I. Thus, in FIGS. **7D-2**A and **7D-3**, fractal ground radial elements **215** are understood to depict any fractal of iteration order N≧1. Further, such fractals may, but need not be, defined by an opening angle.

FIG. **8**A depicts a generalized system in which a transceiver **500** is coupled to a fractal antenna system **510** to send electromagnetic radiation **520** and/or receive electromagnetic radiation **540**. A second transceiver **600** shown equipped with a conventional whip-like vertical antenna **610** also sends electromagnetic energy **630** and/or receives electromagnetic energy **540**.

Fractal antenna system **510** may include a fractal ground counterpoise and/or fractal antenna element, as described earlier herein, and/or a microstrip patch antenna with fractal structure, as described later herein. As noted in the case of a vertical antenna element, the overall size of the resulting antenna system is substantially smaller than what may be achieved with a prior art ground counterpoise system. Further, the fractal ground counterpoise system may be fabricated on a flexible substrate that is rolled, curved, or otherwise formed to fit within a case such as contains transceiver **500**. The resultant antenna ground system exhibits improved efficiency and power distribution pattern relative to a prior art system that may somehow be fit into an equivalent amount of area.

If transceivers **500**, **600** are communication devices such as transmitter-receivers, wireless telephones, pagers, or the like, a communications repeating unit such as a satellite **650** and/or a ground base repeater unit **660** coupled to an antenna **670**, or indeed to a fractal antenna according to the present invention, may be present.

Alternatively, antenna **510** in transceiver **500** could be a passive LC resonator fabricated on an integrated circuit microchip, or other similarly small sized substrate, attached to a valuable item to be protected. Configurations such as shown in exemplary FIGS. **16**–**18** may also be fabricated for antenna **510**, according to the present invention. Transceiver **600**, or indeed unit **660** would then be an electromagnetic transmitter outputting energy at the frequency of resonance, a unit typically located near the cash register checkout area of a store or at an exit. Depending upon whether fractal antenna-resonator **510** is designed to "blow" (e.g., become open circuit) or to "short" (e.g., become a close circuit) in the transceiver **500** will or will not reflect back electromagnetic energy **540** or **6300** to a receiver associated with transceiver **600**. In this fashion, the unauthorized relocation of antenna **510** and/or transceiver **500** can be signaled by transceiver **600**.

FIG. **8**B depicts a transceiver **500** equipped with a plurality of fractal antennas, here shown as **510**A, **510**B, **510**C and **510**D coupled by respective cables **50**A, **50**B, **50**C, **50**D to electronics **600** within unit **500**. In the embodiment shown, one of more of these antenna elements is are fabricated on a conformal, flexible substrate **150**, e.g., Mylar™ material or the like, upon which the antennas per se may be implemented by printing fractal patterns using conductive ink, by copper deposition, among other methods including printed circuit board and semiconductor fabrication techniques. A flexible such substrate may be conformed to a rectangular, cylindrical or other shape as necessary.

In the embodiment of FIG. **8**B, unit **500** is a handheld transceiver, and antennas **510**A, **510**B, **510**C, **510**D preferably are fed for vertical polarization, as shown. Element **510**D may, for example, be a fractal ground counterpoise system for a vertical antenna element, shown in phantom as element **193** (which element may itself be a fractal to further reduce dimensions).

An electronic circuit **610** is coupled by cables **50**A, **50**B, **50**C to the antennas, and samples incoming signals to discern which fractal antenna system, e.g., **510**A, **510**B, **510**C, **510**D is presently most optimally aligned with the transmitting station, perhaps a unit **600** or **650** or **670** as shown in FIG. **8**A. This determination may be made by examining signal strength from each of the antennas. An electronic circuit **620** then selects the presently best oriented antenna, and couples such antenna to the input of the receiver and output of the transmitter portion, collectively **630**, of unit **500**. It is understood that the selection of the best antenna is dynamic and can change as, for example, a user of **500** perhaps walks about holding the unit, or the transmitting source moves, or due to other changing conditions. In a cellular or a wireless telephone application, the result is more reliable communication, with the advantage that the fractal antennas can be sufficiently small-sized as to fit totally within the casing of unit **500**. Further, if a flexible substrate is used, the antennas may be wrapped about portions of the internal casing, as shown.

An additional advantage of the embodiment of FIG. **8**B is that the user of unit **500** may be physically distanced from the antennas by a greater distance that if a conventional external whip antenna were used. Although medical evidence attempting to link cancer with exposure to electromagnetic radiation from handheld transceivers is still inconclusive, the embodiment of FIG. **8**B appears to minimize any such risk. Although FIG. **8**B depicts a vertical antenna **193** and a fractal ground counterpoise **510**D, it is understood that antenna **193** could represent a cellular antenna on a motor vehicle, the ground poise for which is fractal unit **510**D. Further, as noted, vertical element **193** may itself be a fractal.

FIG. **8**C depicts yet another embodiment wherein some or all of the antenna systems **510**A, **510**B, **510**C may include electronically steerable arrays, including arrays of fractal antennas of differing sizes and polarization orientations. Antenna system **510**C, for example may include similarly designed fractal antennas, e.g., antenna F-**3** and F-**4**, which are differently oriented from each other. Other antennas within system **510**C may be different in design from either of F-**3**, F-**4**. Fractal antenna F-**1** may be a dipole for example. Leads from the various antennas in system **510**C may be coupled to an integrated circuit **690**, mounted on substrate **150**. Circuit **690** can determine relative optimum choice between the antennas comprising system **510**C, and output via cable **50**C to electronics **660** associated with the transmitter and/or receiver portion **630** of unit **630**. Of course, the embodiment of FIG. **8**C could also include the vertical antenna element **193** and fractal ground counterpoise **510**D, depicted in FIG. **8**B.

Another antenna system **510**B may include a steerable array of identical fractal antennas, including fractal antenna F-**5** and F-**6**. An integrated circuit **690** is coupled to each of the antennas in the array, and dynamically selects the best antenna for signal strength and coupled such antenna via cable **50**B to electronics **600**. A third antenna system **510**A may be different from or identical to either of system **510**B and **510**C.

Although FIG. **8**C depicts a unit **500** that may be handheld, unit **500** could in fact be a communications system for use on a desk or a field mountable unit, perhaps unit **660** as shown in FIG. **8**A.

For ease of antenna matching to a transceiver load, resonance of a fractal antenna was defined as a total impedance falling between about 20Ω to 200Ω, and the antenna was required to exhibit medium to high Q, e.g., frequency/Δfrequency. In practice, applicants' various fractal antennas were found to resonate in at least one position of the antenna feedpoint, e.g., the point at which coupling was made to the antenna. Further, multi-iteration fractals according to the present invention were found to resonate at multiple frequencies, including frequencies that were non-harmonically related.

Contrary to conventional wisdom, applicant found that island-shaped fractals (e.g., a closed loop-like configuration) do not exhibit significant drops in radiation resistance R for decreasing antenna size. As described herein, fractal antennas were constructed with dimensions of less than 12" across (30.48 cm) and yet resonated in a desired 60 MHz to 100 MHz frequency band.

Applicant further discovered that antenna perimeters do not correspond to lengths that would be anticipated from measured resonant frequencies, with actual lengths being longer than expected. This increase in element length appears to be a property of fractals as radiators, and not a result of geometric construction. A similar lengthening effect was reported by Pfeiffer when constructing a full-sized quad antenna using a first order fractal, see A. Pfeiffer, *The Pfeiffer Quad Antenna System,* QST, p. 28–32 (March 1994).

If L is the total initial one-dimensional length of a fractal pre-motif application, and r is the one-dimensional length post-motif application, the resultant fractal dimension D (actually a ratio limit) is:

$$D=\log(L)/\log(r)$$

With reference to FIG. **1**A, for example, the length of FIG. **1**A represents L, whereas the sum of the four line segments comprising the Koch fractal of FIG. **1**B represents r.

Unlike mathematical fractals, fractal antennas are not characterized solely by the ratio D. In practice D is not a good predictor of how much smaller a fractal design antenna may be because D does not incorporate the perimeter lengthening of an antenna radiating element.

Because D is not an especially useful predictive parameter in fractal antenna design, a new parameter "perimeter compression" ("PC") shall be used, where:

$$PC=\frac{\text{full-sized antenna element length}}{\text{fractal-reduced antenna element length}}$$

In the above equation, measurements are made at the fractal-resonating element's lowest resonant frequency. Thus, for a full-sized antenna according to the prior art PC=1, while PC=3 represents a fractal antenna according to the present invention, in which an element side has been reduced by a factor of three.

Perimeter compression may be empirically represented using the fractal dimension D as follows:

$$PC=A\cdot\log[N(D+C)]$$

where A and C are constant coefficients for a given fractal motif, N is an iteration number, and D is the fractal dimension, defined above.

It is seen that for each fractal, PC becomes asymptotic to a real number and yet does not approach infinity even as the iteration number N becomes very large. Stated differently, the PC of a fractal radiator asymptotically approaches a non-infinite limit in a finite number of fractal iterations. This result is not a representation of a purely geometric fractal.

That some fractals are better resonating elements than other fractals follows because optimized fractal antennas approach their asymptotic PCs in fewer iterations than non-optimized fractal antennas. Thus, better fractals for antennas will have large values for A and C, and will provide the greatest and most rapid element-size shrinkage. Fractal used may be deterministic or chaotic. Deterministic fractals have a motif that replicates at a 100% level on all size scales, whereas chaotic fractals include a random noise component.

Applicant found that radiation resistance of a fractal antenna decreases as a small power of the perimeter compression (PC), with a fractal island always exhibiting a substantially higher radiation resistance than a small Euclidean loop antenna of equal size.

Further, it appears that the number of resonant nodes of a fractal island increase as the iteration number (N) and is always greater than or equal to the number of resonant nodes of an Euclidean island with the same area. Finally, it appears that a fractal resonator has an increased effective wavelength.

The above findings will now be applied to experiments conducted by applicant with fractal resonators shaped into closed-loops or islands. Prior art antenna analysis would predict no resonance points, but as shown below, such is not the case.

A Minkowski motif is depicted in FIGS. **2**B–**2**D, **5**B, **7**C and **7**E. The Minkowski motif selected was a three-sided box (e.g., **20-2** in FIG. **2**B) placed atop a line segment. The box sides may be any arbitrary length, e.g, perhaps a box height and width of 2 units with the two remaining base sides being of length three units (see FIG. **2**B). For such a configuration, the fractal dimension D is as follows:

$$D=\frac{\log(L)}{\log(r)}=\frac{\log(12)}{\log(8)}=\frac{1.08}{0.90}=1.20$$

It will be appreciated that D=1.2 is not especially high when compared to other deterministic fractals.

Applying the motif to the line segment may be most simply expressed by a piecewise function f(x) as follows:

$$\begin{array}{ll} f(x)=0 & 0\geq x\geq\frac{3x_{\max}}{8} \\ f(x)=\frac{1}{4x_{\max}} & \frac{3x_{\max}}{8}\geq x\geq\frac{5x_{\max}}{8} \\ f(x)=0 & \frac{5x_{\max}}{8}\geq x\geq x_{\max} \end{array}$$

where x_{max} is the largest continuous value of x on the line segment.

A second iteration may be expressed as $f(x)_2$ relative to the first iteration $f(x)_1$ by:

$$f(x)_2=f(x)_1+f(x)$$

where x_{max} is defined in the above-noted piecewise function. Note that each separate horizontal line segment will have a different lower value of x and x_{max}. Relevant offsets from zero may be entered as needed, and vertical segments may be "boxed" by 90° rotation and application of the above methodology.

As shown by FIGS. **5**B and **7**E, a Minkowski fractal quickly begins to appear like a Moorish design pattern. However, each successive iteration consumes more perimeter, thus reducing the overall length of an orthogonal line segment. Four box or rectangle-like fractals of the same iteration number N may be combined to create a Minkowski fractal island, and a resultant "fractalized" cubical quad.

An ELNEC simulation was used as a guide to far-field power patterns, resonant frequencies, and SWRs of Minkowski Island fractal antennas up to iteration N=2. Analysis for N>2 was not undertaken due to inadequacies in the test equipment available to applicant.

The following tables summarize applicant's ELNEC simulated fractal antenna designs undertaken to derive lowest frequency resonances and power patterns, to and including iteration N=2. All designs were constructed on the x,y axis, and for each iteration the outer length was maintained at 42" (106.7 cm).

Table 1, below, summarizes ELNEC-derived far field radiation patterns for Minkowski island quad antennas for each iteration for the first four resonances. In Table 1, each iteration is designed as MI-N for Minkowski Island of iteration N. Note that the frequency of lowest resonance decreased with the fractal Minkowski Island antennas, as compared to a prior art quad antenna. Stated differently, for a given resonant frequency, a fractal Minkowski Island antenna will be smaller than a conventional quad antenna.

TABLE 1

Antenna	Res. Freq. MHz	Gain (dBi)	SWR	PC (for 1st)	Direction
Ref. Quad	76	3.3	2.5	1	Broadside
	144	2.8	5.3	—	Endfire
	220	3.1	5.2	—	Endfire
	294	5.4	4.5	—	Endfire
MI-1	55	2.6	1.1	1.38	Broadside
	101	3.7	1.4	—	Endfire
	142	3.5	5.5	—	Endfire
	198	2.7	3.3	—	Broadside
MI-2	43.2	2.1	1.5	1.79	Broadfire
	85.5	4.3	1.8	—	Endfire
	102	2.7	4.0	—	Endfire
	116	1.4	5.4	—	Broadside

It is apparent from Table 1 that Minkowski island fractal antennas are multi-resonant structures having virtually the same gain as larger, full-sized conventional quad antennas. Gain figures in Table 1 are for "free-space" in the absence of any ground plane, but simulations over a perfect ground at 1λ yielded similar gain results. Understandably, there will be some inaccuracy in the ELNEC results due to round-off and undersampling of pulses, among other factors.

Table 2 presents the ratio of resonant ELNEC-derived frequencies for the first four resonance nodes referred to in Table 1.

TABLE 2

Antenna	SWR	SWR	SWR	SWR
Ref. Quad (MI-0)	1:1	1:1.89	1:2.89	3.86:1
MI-1	1:1	1:1.83	1;2.58	3.6:1
MI-2	1:1	2.02:1	2.41:1	2.74:1

Tables 1 and 2 confirm the shrinking of a fractal-designed antenna, and the increase in the number of resonance points. In the above simulations, the fractal MI-2 antenna exhibited four resonance nodes before the prior art reference quad exhibited its second resonance. Near fields in antennas are very important, as they are combined in multiple-element antennas to achieve high gain arrays. Unfortunately, programming limitations inherent in ELNEC preclude serious near field investigation. However, as described later herein, applicant has designed and constructed several different high gain fractal arrays that exploit the near field.

Applicant fabricated three Minkowski Island fractal antennas from aluminum #8 and/or thinner #12 galvanized groundwire. The antennas were designed so the lowest operating frequency fell close to a desired frequency in the 2 M (144 MHz) amateur radio band to facilitate relative gain measurements using 2 M FM repeater stations. The antennas were mounted for vertical polarization and placed so their center points were the highest practical point above the mounting platform. For gain comparisons, a vertical ground plane having three reference radials, and a reference quad were constructed, using the same sized wire as the fractal antenna being tested. Measurements were made in the receiving mode.

Multi-path reception was minimized by careful placement of the antennas. Low height effects were reduced and free space testing approximated by mounting the antenna test platform at the edge of a third-store window, affording a 3.5λ height above ground, and line of sight to the repeater, 45 miles (28 Km) distant. The antennas were stuck out of the window about 0.8λ from any metallic objects and testing was repeated on five occasions from different windows on the same floor, with test results being consistent within ½ dB for each trial.

Each antenna was attached to a short piece of 9913 50Ω coaxial cable, fed at right angles to the antenna. A 2 M transceiver was coupled with 9913 coaxial cable to two precision attenuators to the antenna under test. The transceiver S-meter was coupled to a volt-ohm meter to provide signal strength measurements The attenuators were used to insert initial threshold to avoid problems associated with non-linear S-meter readings, and with S-meter saturation in the presence of full squelch quieting.

Each antenna was quickly switched in for volt-ohmmeter measurement, with attenuation added or subtracted to obtain the same meter reading as experienced with the reference quad. All readings were corrected for SWR attenuation. For the reference quad, the SWR was 2.4:1 for 120Ω impedance, and for the fractal quad antennas SWR was less than 1.5:1 at resonance. The lack of a suitable noise bridge for 2 M precluded efficiency measurements for the various antennas. Understandably, anechoic chamber testing would provide even more useful measurements.

For each antenna, relative forward gain and optimized physical orientation were measured. No attempt was made to correct for launch-angle, or to measure power patterns other than to demonstrate the broadside nature of the gain. Difference of ½ dB produced noticeable S-meter deflections, and differences of several dB produced substantial meter deflection. Removal of the antenna from the receiver resulted in a 20^{+} dB drop in received signal strength. In this fashion, system distortions in readings were cancelled out to provide more meaningful results. Table 3 summarizes these results.

TABLE 3

Antenna	PC	PL	SWR	Cor. Gain (dB)	Sidelength (λ)
Quad	1	1	2.4:1	0	0.25
1/4 wave	1	—	1.5:1	−1.5	0.25
MI-1	1.3	1.2	1.3:1	1.5	0.13
MI-2	1.9	1.4	1.3:1	1.5	0.13
MI-3	2.4	1.7	1:1	−1.2	0.10

It is apparent from Table 3 that for the vertical configurations under test, a fractal quad according to the present invention either exceeded the gain of the prior art test quad, or had a gain deviation of not more than 1 dB from the test quad. Clearly, prior art cubical (square) quad antennas are not optimized for gain. Fractally shrinking a cubical quad by a factor of two will increase the gain, and further shrinking will exhibit modest losses of 1–2 dB.

Versions of a MI-2 and MI-3 fractal quad antennas were constructed for the 6 M (50 MHz) radio amateur band. An RX 50Ω noise bridge was attached between these antennas and a transceiver. The receiver was nulled at about 54 MHz and the noise bridge was calibrated with 5Ω and 10Ω resistors. Table 4 below summarizes the results, in which almost no reactance was seen.

TABLE 4

Antenna	SWR	Z(Ω)	O(Ω)	E(%)
Quad (MI-0)	2.4:1	120	5–10	92–96
MI-2	1.2:1	60	≦5	≧92
MI-3	1.1:1	55	≦5	≧91

In Table 4, efficiency (E) was defined as 100%*(R/Z), where Z was the measured impedance, and R was Z minus ohmic impedance and reactive impedances (0). As shown in Table 4, fractal MI-2 and MI-3 antennas with their low ≦1.2:1 SWR and low ohmic and reactive impedance provide extremely high efficiencies, $90^{+}\%$. These findings are indeed surprising in view of prior art teachings stemming from early Euclidean small loop geometries. In fact, Table 4 strongly suggests that prior art associations of low radiation impedances for small loops must be abandoned in general, to be invoked only when discussing small Euclidean loops. Applicant's MI-3 antenna was indeed micro-sized, being dimensioned at about 0.1λ per side, an area of about $\lambda^2/1{,}000$, and yet did not signal the onset of inefficiency long thought to accompany smaller sized antennas.

However the 6M efficiency data do not explain the fact that the MI-3 fractal antenna had a gain drop of almost 3 dB relative to the MI-2 fractal antenna. The low ohmic impedances of ≦5Ω strongly suggest that the explanation is other than inefficiency, small antenna size notwithstanding. It is quite possible that near field diffraction effects occur at higher iterations that result in gain loss. However, the smaller antenna sizes achieved by higher iterations appear to warrant the small loss in gain.

Using fractal techniques, however, 2 M quad antennas dimensioned smaller than 3" (7.6 cm) on a side, as well as 20 M (14 MHz) quads smaller than 3' (1 m) on a side can be realized. Economically of greater interest, fractal antennas constructed for cellular telephone frequencies (850 MHz) could be sized smaller than 0.5" (1.2 cm). As shown by FIGS. **8**B and **8**C, several such antenna, each oriented differently could be fabricated within the curved or rectilinear case of a cellular or wireless telephone, with the antenna outputs coupled to a circuit for coupling to the most optimally directed of the antennas for the signal then being received. The resultant antenna system would be smaller than the "rubber-ducky" type antennas now used by cellular telephones, but would have improved characteristics as well.

Similarly, fractal-designed antennas could be used in handheld military walkie-talkie transceivers, global positioning systems, satellites, transponders, wireless communication and computer networks, remote and/or robotic control systems, among other applications. Although the fractal Minkowski island antenna has been described herein, other fractal motifs are also useful, as well as non-island fractal configurations.

Table 5 demonstrates bandwidths ("BW") and multi-frequency resonances of the MI-2 and MI-3 antennas described, as well as Qs, for each node found for 6 M versions between 30 MHz and 175 MHz. Irrespective of resonant frequency SWR, the bandwidths shown are SWR 3:1 values. Q values shown were estimated by dividing resonant frequency by the 3:1 SWR BW. Frequency ratio is the relative scaling of resonance nodes.

TABLE 5

Antenna	Freq. (MHz)	Freq. Ratio	SWR	3:1 BW	Q
MI-3	53.0	1	1:1	6.4	8.3
	80.1	1.5:1	1.1:1	4.5	17.8
	121.0	2.3:1	2.4:1	6.8	17.7
MI-2	54.0	1	1:1	3.6	15.0
	95.8	1.8:1	1.1:1	7.3	13.1
	126.5	2.3:1	2.4:1	9.4	13.4

The Q values in Table 5 reflect that MI-2 and MI-3 fractal antennas are multiband. These antennas do not display the very high Qs seen in small tuned Euclidean loops, and there is a lack of a mathematical application to electromagnetics to predict these resonances or Qs. One approach might be to estimate scalar and vector potentials in Maxwell's equations by regarding each Minkowski Island iteration as a series of vertical and horizontal line segments with offset positions. Summation of these segments will lead to a Poynting vector calculation and power pattern that may be especially useful in better predicting fractal antenna characteristics and optimized shapes. In practice, actual Minkowski Island fractal antennas seem to perform slightly better than their ELNEC predictions, most likely due to inconsistencies in ELNEC modeling or ratios of resonant frequencies, PCs, SWRs and gains.

Those skilled in the art will appreciate that fractal multiband antenna arrays may also be constructed. Such arrays will be smaller and present less wind area than their Euclidean counterparts, and are mechanically rotatable with a smaller antenna rotator. Fractal antenna configurations using other than Minkowski islands or loops may be implemented. Table 6 shows the highest iteration number N for other fractal configurations that were found by applicant to resonant on at least one frequency.

FIG. **9**A depicts gain relative to an Euclidean quad (e.g., an MI-0) configuration as a function of iteration value N. (It is understood that an Euclidean quad exhibits 1.5 dB gain relative to a standard reference dipole.) For first and second order iterations, the gain of a fractal quad increases relative to an Euclidean quad. However, beyond second order, gain drops off relative to an Euclidean quad. Applicant believes that near field electromagnetic energy diffraction-type cancellations may account for the gain loss for N>2. Possibly the far smaller areas found in fractal antennas according to the present invention-bring this diffraction phenomenon into sharper focus.

n practice, applicant could not physically bend wire for a 4th or 5th iteration 2 M Minkowski fractal antenna, although at lower frequencies the larger antenna sizes would not present this problem. However, at higher frequencies, printed circuitry techniques, semiconductor fabrication techniques as well as machine-construction could readily produce N=4, N=5, and higher order iterations fractal antennas.

In practice, a Minkowski island fractal antenna should reach the theoretical gain limit of about 1.7 dB seen for sub-wavelength Euclidean loops, but N will be higher than 3. Conservatively, however, an N=4 Minkowski Island fractal quad antenna should provide a PC=3 value without exhibiting substantial inefficiency.

FIG. **9**B depicts perimeter compression (PC) as a function of iteration order N for a Minkowski island fractal configuration. A conventional Euclidean quad (MI-0) has PC=1 (e.g., no compression), and as iteration increases, PC increases. Note that as N increases and approaches 6, PC approaches a finite real number asymptotically, as predicted.

Thus, fractal Minkowski Island antennas beyond iteration N=6 may exhibit diminishing returns for the increase in iteration.

It will be appreciated that the non-harmonic resonant frequency characteristic of a fractal antenna according to the present invention may be used in a system in which the frequency signature of the antenna must be recognized to pass a security test. For example, at suitably high frequencies, perhaps several hundred MHz, a fractal antenna could be implemented within an identification credit card. When the card is used, a transmitter associated with a credit card reader can electronically sample the frequency resonance of the antenna within the credit card. If and only if the credit card antenna responds with the appropriate frequency signature pattern expected may the credit card be used, e.g., for purchase or to permit the owner entrance into an otherwise secured area.

FIG. **10**A depicts a fractal inductor L according to the present invention. In contrast to a prior art inductor, the winding or traces with which L is fabricated define, at least in part, a fractal. The resultant inductor is physically smaller than its Euclidean counterpart. Inductor L may be used to form a resonator, including resonators such as shown in FIGS. **4**A and **4**B. As such, an integrated circuit or other suitably small package including fractal resonators could be used as part of a security system in which electromagnetic radiation, perhaps from transmitter **600** or **660** in FIG. **8**A will blow, or perhaps not blow, an LC resonator circuit containing the fractal antenna. Such applications are described elsewhere herein and may include a credit card sized unit **700**, as shown in FIG. **10**B, in which an LC fractal resonator **710** is implemented. (Card **700** is depicted in FIG. **10**B as though its upper surface were transparent.).

The foregoing description has largely replicated what has been set forth in applicant's above-noted FRACTAL ANTENNAS AND FRACTAL RESONATORS patent application. The following section will set forth methods and techniques for tuning such fractal antennas and resonators. In the following description, although the expression "antenna" may be used in referring to a preferably fractal element, in practice what is being described is an antenna or filter-resonator system. As such, an "antenna" can be made to behave as through it were a filter, e.g., passing certain frequencies and rejecting other frequencies (or the converse).

In one group of embodiments, applicant has discovered that disposing a fractal antenna a distance Δ that is in close proximity (e.g., less than about 0.05λ for the frequency of interest) from a conductor advantageously can change the resonant properties and radiation characteristics of the antenna (relative to such properties and characteristics when such close proximity does not exist, e.g., when the spaced-apart distance is relatively great. For example, in FIG. **11**A a conductive surface **800** is disposed a distance Δ behind or beneath a fractal antenna **810**, which in FIG. **11**A is a single arm of an MI-2 fractal antenna. Of course other fractal configurations such as disclosed herein could be used instead of the MI-1 configuration shown, and non-planar configurations may also be used. Fractal antenna **810** preferably is fed with coaxial cable feedline **50**, whose center conductor is attached to one end **815** of the fractal antenna, and whose outer shield is grounded to the conductive plane **800**. As described herein, great flexibility in connecting the antenna system shown to a preferably coaxial feedline exists. Termination impedance is approximately of similar magnitudes as described earlier herein.

In the configuration shown, the relative close proximity between conductive sheet **800** and fractal antenna **810** lowers the resonant frequencies and widens the bandwidth of antenna **810**. The conductive sheet **800** may be a plane of metal, the upper copper surface of a printed circuit board, a region of conductive material perhaps sprayed onto the housing of a device employing the antenna, for example the interior of a transceiver housing **500**, such as shown in FIGS. **8**A, **8**B, **8**C, and **15**.

The relationship between Δ, wherein $\Delta \leqq 0.05\lambda$, and resonant properties and radiation characteristics of a fractal antenna system is generally logarithmic. That is, resonant frequency decreases logarithmically with decreasing separation Δ.

FIG. **11**B shows an embodiment in which a preferably fractal antenna **810** lies in the same plane as a ground plane **800** but is separated therefrom by an insulating region, and in which a passive or parasitic element **800'** is disposed "within" and spaced-apart a distance Δ' from the antenna, and also being coplanar. For example, the embodiment of FIG. **11**B may be fabricated from a single piece of printed circuit board material in which copper (or other conductive material) remains to define the groundplane **800**, the antenna **810**, and the parasitic element **800'**, the remaining portions of the original material having been etched away to form the "moat-like" regions separating regions **800**, **810**, and **800'**. Changing the shape and/or size of element **800'** and/or the coplanar spaced-apart distance Δ' tunes the antenna system shown. For example, for a center frequency in the 900 MHz range, element **800'** measured about 63 mm×8 mm, and elements **810** and **800** each measured about 25 mm×12 mm.

In general, element **800** should be at least as large as the preferably fractal antenna **810**. For this configuration, the system shown exhibited a bandwidth of about 200 MHz, and could be made to exhibit characteristics of a bandpass filter and/or band rejection filter. In this embodiment, a coaxial feedline **50** was used, in which the center lead was coupled to antenna **810**, and the ground shield lead was coupled to groundplane **800**. In FIG. **11**B, the inner perimeter of groundplane region **800** is shown as being rectangularly shaped. If desired, this inner perimeter could be moved closer to the outer perimeter of preferably fractal antenna **810**, and could in fact define a perimeter shape that follows the perimeter shape of antenna **810**. In such an embodiment, the perimeter of the inner conductive region **800'** and the inner perimeter of the ground plane region **800** would each follow the shape of antenna **810**. Based upon experiments to date, it is applicant's belief that moving the inner perimeter of ground plane region **800** sufficiently close to antenna **810** could also affect the characteristics of the overall antenna/resonator system.

Referring now to FIG. **12**A, if the conductive surface **800** is replaced with a second fractal antenna **810'**, which is spaced-apart a distance Δ that preferably does not exceed about 0.05λ, resonances for the radiating fractal antenna **810** are lowered and advantageously new resonant frequencies emerge. For ease of fabrication, it may be desired to construct antenna **810** on the upper or first surface **820**A of a substrate **820**, and to construct antenna **810'** on the lower or second surface **820**B of the same substrate. The substrate could be doubled-side printed circuit board type material, if desired, wherein antennas **810**, **810'** are fabricated using printed circuit type techniques. The substrate thickness Δ is selected to provide the desired performance for antenna **810** at the frequency of interest. Substrate **820** may, for example, be a non-conductive film, flexible or otherwise. To avoid cluttering FIGS. **12**A and **12**B, substrate **820** is drawn with phantom lines, as if the substrate were transparent.

As noted earlier, the fractal spaced-apart structure depicted in FIGS. **12**A and **12**B may instead be used to form a fractal element in a vertical antenna system, preferably including a fractal ground counterpoise, such as was described with respect to FIG. **8**D-**3**.

Preferably, the center conductor of coaxial cable **50** is connected to one end **815** of antenna **810**, and the outer conductor of cable **50** is connected to a free end **815'** of antenna **810'**,which is regarded as ground, although other feedline connections may be used. Although FIG. **12**A depicts antenna **810'** as being substantially identical to antenna **810**, the two antennas could in fact have different configurations.

Applicant has discovered that if the second antenna **810'** is rotated some angle Θ relative to antenna **810**, the resonant frequencies of antenna **810** may be varied, analogously to tuning a variable capacitor. Thus, in FIG. **12**B, antenna **810** is tuned by rotating antenna **810'** relative to antenna **810** (or the converse, or by rotating each antenna). If desired, substrate **820** could comprise two substrates each having thickness Δ/2 and pivotally connected together, e.g., with a non-conductive rivet, so as to permit rotation of the substrates and thus relative rotation of the two antennas. Those skilled in the mechanical arts will appreciate that a variety of "tuning" mechanisms could be implemented to permit fine control over the angle Θ in response, for example, to rotation of a tunable shaft.

Referring now to FIG. **13**A, applicant has discovered that creating at least one cut or opening **830** in a fractal antenna **810** (here comprising two legs of an MI-2 antenna) results in new and entirely different resonant nodes for the antenna. Further, these nodes can have perimeter compression (PC) ranging from perhaps three to about ten. The precise location of cut **830** on the fractal antenna or resonator does not appear to be critical.

FIGS. **13**B and **13**C depict a self-proximity characteristic of fractal antennas and resonators that may advantageously be used to create a desired frequency resonant shift. In FIG. **13**B, a fractal antenna **810** is fabricated on a first surface **820**A of a flexible substrate **820**, whose second surface **820**B does not contain an antenna or other conductor in this embodiment. Curving substrate **820**, which may be a flexible film, appears to cause electromagnetic fields associated with antenna **810** to be sufficiently in self-proximity so as to shift resonant frequencies. Such self-proximity antennas or resonators may be referred to a com-cyl devices. The extent of curvature may be controlled where a flexible substrate or substrate-less fractal antenna and/or conductive element is present, to control or tune frequency dependent characteristics of the resultant system. Com-cyl embodiments could include a concentrically or eccentrically disposed fractal antenna and conductive element. Such embodiments may include telescopic elements, whose extent of "overlap" may be telescopically adjusted by contracting or lengthening the overall configuration to tune the characteristics of the resultant system. Further, more than two elements could be provided.

In FIG. **13**C, a fractal antenna **810** is formed on the outer surface **820**A of a filled substrate **820**, which may be a ferrite core. The resultant com-cyl antenna appears to exhibit self-proximity such that desired shifts in resonant frequency are produced. The geometry of the core **820**, e.g., the extent of curvature (e.g., radius in this embodiment) relative to the size of antenna **810** may be used to determine frequency shifts.

In FIG. **14**A, an antenna or resonator system is shown in which the non-driven fractal antenna **810'** is not connected to the preferably coaxial feedline **50**. The ground shield portion of feedline **50** is coupled to the groundplane conductive element **800**, but is not otherwise connected to a system ground. Of course fractal antenna **810'** could be angularly rotated relative to driven antenna **810**, it could be a different configuration than antenna **810** including having a different iteration N, and indeed could incorporate other features disclosed herein (e.g., a cut).

FIG. **14**B demonstrates that the driven antenna **810** may be coupled to the feedline **50** at any point **815'**, and not necessarily at an end point **8'5** as was shown in FIG. **14**A.

In the embodiment of FIG. **14**C, a second ground plane element **800'** is disposed adjacent at least a portion of the system comprising driven antenna **810**, passive antenna **810'**, and the underlying conductive planar element **800**. The presence, location, geometry, and distance associated with second ground plane element **800'** from the underlying elements **810**, **810'**, **800** permit tuning characteristics of the overall antenna or resonator system. In the multi-element sandwich-like configuration shown, the ground shield of conductor **50** is connected to a system ground but not to either ground plane **800** or **800'**. Of course more than three elements could be used to form a tunable system according to the present invention.

FIG. **14**D shows a single fractal antenna spaced apart from an underlying ground plane **800** a distance Δ, in which a region of antenna **800** is cutaway to increase resonance. In FIG. **14**D, for example, L**1** denotes a cutline, denoting that portions of antenna **810** above (in the Figure drawn) L**1** are cutaway and removed. So doing will increase the frequencies of resonance associated with the remaining antenna or resonator system. On the other hand, if portions of antenna **810** above cutline L**2** are cutaway and removed, still higher resonances will result. Selectively cutting or etching away portions of antenna **810** permit tuning characteristics of the remaining system.

As noted, fractal elements similar to what is generically depicted in FIGS. **14**A–**14**D may be used to form a fractal vertical element in a fractal vertical antenna system, such as was described with respect to FIG. **7**D-**3**.

FIG. **15** depicts an embodiment somewhat similar to what has been described with respect to FIG. **8**B or FIG. **8**C. Once again unit **500** is a handheld transceiver, and includes fractal antennas **510**A, **510**B–**510**B', **510**C. It is again understood that a vertical antenna such as elements **193** and fractal counterpoise **510**D (shown in FIG. **8**B) may be provided. Antennas **510**B–**510**B' are similar to what has been described with respect to FIGS. **12**A–**12**B. Antennas **510**B–**510**B' are fractal antennas, not necessarily MI-2 configuration as shown, and are spaced-apart a distance Δ and, in FIG. **13**, are rotationally displaced. Collectively, the spaced-apart distance and relative rotational displacement permits tuning the characteristics of the driven antenna, here antenna **510**B. In FIG. **14**, antenna **510**A is drawn with phantom lines to better distinguish it from spaced-apart antenna **510**B. Of course passive conductor **510**B' could instead be a solid conductor such as described with respect to FIG. **11**A. Such conductor may be implemented by spraying the inner surface of the housing for unit **500** adjacent antenna **510**B with conductive paint.

In FIG. **15**, antenna **510**C is similar to what has been described with respect to FIG. **13**A, in that a cut **830** is made in the antenna, for tuning purposes. Although antenna **510**A is shown similar to what was shown in FIG. **8**B, antenna **510**A could, if desired, be formed on a curved substrate similar to FIGS. **13**B or **13**C. While FIG. **15** shows at least two different techniques for tuning antennas according to the present invention, it will be understood that a common technique could instead be used. By that it is meant that any or all of antennas **510**A, **510**B–**510**B', **510**C could include a cut, or be spaced-apart a controllable distance Δ, or be rotatable relative to a spaced-apart conductor.

As described with respect to FIG. **8**B, an electronic circuit **610** may be coupled by cables **50**A, **50**B, **50**C to the antennas, and samples incoming signals to discern which fractal antenna, e.g., **510**A, **510**B–**510**B', **510**C (and, if present, antenna **510**D-**197**) is presently most optimally aligned with the transmitting station, perhaps a unit **600** or **650** or **670** as shown in FIG. **8**A. This determination may be made by examining signal strength from each of the antennas. An electronic circuit **620** then selects the presently best oriented antenna, and couples such antenna to the input of the receiver and output of the transmitter portion, collectively **630**, of unit **500**. It is understood that the selection of the best antenna is dynamic and can change as, for example, a user of **500** perhaps walks about holding the unit, or the transmitting source moves, or due to other changing conditions. In a cellular or a wireless telephone application, the result is more reliable communication, with the advantage that the fractal antennas can be sufficiently small-sized as to fit totally within the casing of unit **500**. Further, if a flexible substrate is used, the antennas may be wrapped about portions of the internal casing, as shown.

An additional advantage of the embodiment of FIG. **8**B is that the user of unit **500** may be physically distanced from the antennas by a greater distance that if a conventional external whip antenna were used. Although medical evidence attempting to link cancer with exposure to electromagnetic radiation from handheld transceivers is still inconclusive, the embodiment of FIG. **8**B appears to minimize any such risk.

Turning now to FIGS. **16**–**18**, in FIG. **16**, a microstrip patch antenna **10** according to the present invention is shown coupled by coaxial or other cable (or equivalent) **20** to a source of radio frequency **30**. Antenna **10** comprises a substrate **40** whose top-to-bottom thickness is preferably substantially less than one wavelength at the frequency of interest, e.g., the radio frequency or band of radio frequencies coupled by cable **20** to antenna **10**. Preferably the effective dimension of substrate is one-eighth wavelength at such frequency.

On its first surface, substrate **40** is initially covered by a conductive layer of material **50** that is etched away or otherwise removed in areas other than the desired fractal pattern (**60**) design, to expose the substrate. The remaining conductive trace portion defines a fractal element, according to the present invention.

Similarly on its second surface, substrate **40** is initially covered by a conductive layer of material **70** that is selectively removed so as to leave a desired pattern (**80**) that may also be a fractal pattern, according to the present invention. Alternatively, conductive material defining the desired patterns **60**, **80** could be deposited upon substrate **40**, rather than beginning fabrication with a substrate clad or otherwise having conductive surfaces, portions of which are removed.

Preferably feedtabs **90** and **100** are coupled, respectively, to edge regions of the first and second surfaces of substrate **40** to facilitate electrical radio frequency coupling between cable **20** and patterns **60** and/or **80**. These feedtabs preferably are etched using the same conductive material originally found on the upper or lower surfaces of substrate **40**, or may otherwise be formed using techniques known to those skilled in the relevant art. If patterns **60** and **80** are deposited rather than etched, then feedtabs **90**, **100** may be deposited at the same fabrication step.

Substrate **40** is a non-conductive material, and by way of example may be a silicon wafer, a rigid or a flexible plastic-like material, perhaps Mylar™ material, or the non-conductive portion of a printed circuit board, paper, epoxy, among other materials. The original conductive material on the first and/or second surfaces may be deposited doped polysilicon for a semiconductor substrate **40**, or copper (or other conductor) for a printed circuit board substrate.

FIG. **17** is a plan view of one surface of antenna **10** (it matters not which), and depicts a first iteration fractal conductive pattern, although a fractal pattern with higher than first iteration could instead be used. The pattern shown in FIG. **2** is often referred to as a Sierpinski (square) gasket pattern. A margin is shown in FIG. **17** between the outer perimeter of the pattern and the edge of the substrate; however no such margin is required. Although FIG. **2** shows inclusion of feedtab **90** or **100**, radio frequency feed may be made elsewhere on the surface, for example at any point **110**.

If the fractal pattern of FIG. **17** represents one surface of antenna **10**, the opposite surface need not define a fractal pattern, but may in fact do so. For example, one surface may define a fractal pattern and the opposite surface may be entirely conductive, or may define on the substrate a conductive circle, etc. If the pattern on the opposite surface is also a fractal, there is no requirement that it be the same iteration fractal as is defined on the first surface, or that it be the same fractal type. While common fractal families include Koch, Minkowski, Julia, diffusion limited aggregates, fractal trees, Mandelbrot, microstrip patch antennas with fractal element(s) according to the present invention may be implemented with other fractals as well.

FIG. **18** depicts a pattern **60** or **80** in which a different fractal pattern is defined, a so-called diffusion limited aggregate pattern. It is understood, however, that according to the present invention, a great variety of fractal patterns of first or higher iteration may be defined on the first and/or second surface of antenna **10**. In FIG. **18**, while a feedtab **90** or **100** is shown, it is again understood that radio frequency feed may be made essentially anywhere on the fractal pattern, e.g., at a point **110**.

In one embodiment, applicant fabricated an antenna **10** having sides dimensioned to about one-eighth wavelength for a frequency of about 900 MHz. Those skilled in the art will readily appreciate that a microstrip patch antenna dimensioned to one-eighth wavelength is substantially smaller than prior art non-fractal microstrip patch antennas, in which dimensions are one-quarter or one-half wavelength in size. At 900 MHz, bandwidth was about 5% to about 8% of nominal frequency. Gain and matching impedance were acceptable, and indeed substantially 50Ω impedance is realized without the need for impedance transforming devices.

Modifications and variations may be made to the disclosed embodiments without departing from the subject and spirit of the invention as defined by the following claims. While common fractal families include Koch, Minkowski, Julia, diffusion limited aggregates, fractal trees, Mandelbrot, ground counterpoise elements and/or top-hat loading elements according to the present invention may be implemented with other fractals as well.

What is claimed is:

1. An antenna system including:

a driven element, and

at least one element a portion of which is a fractal element selected from a group consisting of (a) a fractal counterpoise, and (b) a microstrip patch element; wherein the fractal element is defined as a superposition over at least N=1 iterations of a fractal generator motif, an iteration being placement of said fractal generator motif upon a base figure through at least one positioning selected from the group consisting of (i) rotation, (ii) stretching, and (iii) translation,

wherein said system includes a substrate having (1) spaced-apart first and second surfaces and (2) a substrate thickness substantially less than a wavelength at a frequency to be coupled to said antenna system; and said driven element is fabricated on the first surface of said substrate.

2. The antenna system of claim **1**, wherein said substrate is flexible.

3. The antenna system of claim **1**, wherein said fractal generator motif has x-axis, y-axis coordinates for a next iteration N+1 defined by $X_{N+1}=f(x_N, y_N)$ and $y_{N+1}=g(x_N, y_N)$, where x_N, y_N are coordinates for iteration N, and where f(x,y) and g(x,y) are functions defining said fractal generator motif and behavior.

4. The antenna system of claim **3**, wherein said fractal generator motif is selected from a family consisting of (i)-Koch, (ii) Minkowski, (iii-) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski gasket, and (ix) Julia.

5. The antenna system of claim **1**, in which said fractal counterpoise is fabricated in a manner selected from the group consisting of (i) shaping conductive wire into said fractal, (ii) forming upon an insulator substrate a conductive layer defining traces shaped to form said fractal, (iii) forming upon a flexible insulator substrate conductive traces shaped to form said fractal; and (iv) forming upon a semiconductor substrate a layer of conductive material shaped to form said fractal.

6. The antenna system of claim **1**, wherein said system is an antenna selected from a group consisting of (i) a fractal quad, (ii) an $N\geqq3$ iteration fractal quad, (iii) a Minkowski fractal quad, (iv) a dipole, (vi) a vertical, and (vii) a microstrip patch antenna.

7. A fractal antenna coupleable to a transceiver unit, the antenna comprising:

a driven element, and

at least one fractal element selected from a group consisting of (a) a fractal counterpoise, and (b) a microstrip patch element, said fractal element having a physical shape defined substantially as a deterministic fractal of iteration $N\geqq2$ for at least a portion of said element;

wherein said antenna includes a substrate having (1) spaced-apart first and second surfaces and a substrate thickness substantially less than a wavelength at a frequency to be coupled to said antenna system: and said driven element is fabricated on the first surface of said substrate.

8. The antenna of claim **7**, wherein said fractal is defined as a superposition over at least N=2 iterations of a fractal generator motif, an iteration being placement of said fractal generator motif upon a base figure through at least one positioning selected from the group consisting of (i) rotation, (ii) stretching, and (iii) translation.

9. The antenna of claim **8**, wherein said driven element has at least one characteristic selected from a group consisting of (a) said driven element defined by a fractal, (b) said driven element is formed as a microstrip patch antenna, (c) said driven element is formed on a substrate, and (c) said driven element is formed on a flexible substrate.

10. The antenna of claim **7**, in which said transceiver unit is hand holdable in size, and wherein said antenna is mounted within a housing of said transceiver unit, and said antenna is fabricated in a manner selected from the group consisting of (i) shaping conductive wire into said fractal, (ii) forming upon an insulator substrate a conductive layer defining traces shaped to form said fractal, (iii) forming upon a flexible insulator substrate conductive traces shaped to form said fractal; and (iv) forming upon a semiconductor substrate a layer of conductive material shaped to form said fractal.

11. The antenna of claim **7**, wherein said transceiver includes a plurality of said antennas in at least one configuration selected from the group consisting of (i) an array of substantially identical said antennas coupled to an electronic circuit that dynamically selects a chosen one of said antennas to be coupled to said transceiver unit, (ii) an array of substantially identical said antennas coupled to an electronic circuit that dynamically selects a chosen one of said antennas to be coupled to said transceiver unit, at least two antennas in said array having orientation differing from other antennas in said plurality, (iii) a plurality of antennas in which at least two antennas have elements differing from elements in other of said antennas.

12. The antenna of claim **7**, wherein said driven element includes a fractal element and a conductive element, spaced-apart from said fractal element by a distance Δ sufficiently small at a frequency of interest λ to decrease said at least one resonant frequency, to widen said bandwidth, or to cause a combination thereof.

13. The antenna of claim **12**, wherein said antenna is tunable by varying at least one parameter selected from the group consisting of (a) said distance Δ, (b) relative rotation between said first and said second fractal antenna, (c) location at which a feedline center lead is coupled to said first fractal antenna, (d) location of a cut in said first fractal antenna, and (e) size of a region of said first fractal antenna cutaway and removed.

14. A top-hat loaded antenna, comprising:

a vertical element having an upper end and a lower end; and

a top-hat assembly electrically coupled to said upper end of said vertical element;

wherein said top-hat assembly includes at least one element whose physical shape is defined substantially as a deterministic fractal of iteration $N\geqq2$ for at least a portion of said element.

RELATED APPLICATIONS AND TECHNICAL FIELD

This application is a continuation of U.S. patent application Ser. No. 11/210,978 filed 24 Aug. 2005, which claims priority to U.S. Provisional Patent Application Ser. No. 60/603,882, filed Aug. 24, 2004, the entire contents of both of which application are incorporated herein by reference. This application is also a continuation-in-part of U.S. patent application Ser. No. 11/778,734 (FRTK-1CN6) filed 17 Jul. 2007, which is a continuation of U.S. patent application Ser. No. 10/243,444 (FRTK-1CN5) filed 13 Sep. 2002, which is a continuation of U.S. application Ser. No. 08/512,954 (FRTK-1) filed 9 Aug. 1995, now issued as U.S. Pat. No. 6,452,553; this application is also a continuation-in-part of U.S. patent application Ser. No. 11/390,323 (FRTK-3CN2CN) filed 27 Mar. 2006, which is a continuation of U.S. patent application Ser. No. 10/287,240 (FRTK-3CN2) filed 4 Nov. 2002, which in turn is a continuation of U.S. patent application Ser. No. 09/677,645 (FRTK-3CN) filed 3 Oct. 2000, which in turn is a continuation of both U.S. patent application Ser. No. 08/967,375 (FRTK-1CN4) filed 7 Nov. 1997 and U.S. patent application Ser. No. 08/965,914 (FRTK-3) filed 7 Nov. 1997, issued as U.S. Pat. No. 6,127,977 (3 Oct. 2000); this application is also a continuation-in-part of U.S. patent application Ser. No. 11/867,284 (FRTK-6CN2) filed 4 Oct. 2007, which is a continuation of U.S. patent application Ser. No. 11/327,982 (FRTK-6CN) filed 9 Jan. 2006, which is a continuation of U.S. patent application Ser. No. 10/971,815 (FRTK-6) filed Oct. 22, 2004 now issued as U.S. Pat. No. 6,985,122, which claimed priority to U.S. Provisional Patent Application Ser. No. 60/513,497, filed Oct. 22, 2003.

This application is also related to the following U.S. application, of common assignee, and the contents of which are incorporated herein in their entirety by reference: "Antenna System for Radio Frequency Identification," U.S. patent application Ser. No. 10/971,815 (FRTK-6) filed 22 Oct. 2004.

This disclosure relates to antenna systems and, more particularly, to wideband antennas that are incorporated into garments.

BACKGROUND

Antennas are used to typically radiate and/or receive electromagnetic signals, preferably with antenna gain, directivity, and efficiency. Practical antenna design traditionally involves trade-offs between various parameters, including antenna gain, size, efficiency, and bandwidth.

Antenna design has historically been dominated by Euclidean geometry. In such designs, the closed area of the antenna is directly proportional to the antenna perimeter. For example, if one doubles the length of an Euclidean square (or "quad") antenna, the enclosed area of the antenna quadruples. Classical antenna design has dealt with planes, circles, triangles, squares, ellipses, rectangles, hemispheres, paraboloids, and the like.

With respect to antennas, prior art design philosophy has been to pick a Euclidean geometric construction, e.g., a quad, and to explore its radiation characteristics, especially with emphasis on frequency resonance and power patterns. Unfortunately antenna design has concentrated on the ease of antenna construction, rather than on the underlying electromagnetics, which can cause a reduction in antenna performance.

Antenna systems that incorporate a Euclidean geometry include man-portable communication antennas such as monopole antennas. Typically these types of antennas include a wire or rod that may be extended to a deployed position that is located above the antenna carrier's head. As such, these extendable antennas may provide a visual signature that may disclose the location of the person carrying the antenna (such as a soldier in the field). Additionally, these antennas implement a monopole design that typically exhibit a narrow instantaneous bandwidth.

SUMMARY OF THE DISCLOSURE

In accordance with an aspect of the disclosure, a portable antenna system includes an antenna that is substantially defined by one or more portions that include electrically conductive self-similar extensions. The system also includes an article of clothing in which the antenna is attached to a surface of the article of clothing such that electrically conductive self-similar extensions extend across the surface of the article of clothing.

In one embodiment, the self-similar extensions may include two or more angular bends. The system may further include a co-planar feed connected to the antenna for transmitting and/or receiving electromagnetic signals through the antenna. Each self-similar extension may incorporate a fractal geometry. Furthermore, the antenna may transmit and/or receive electromagnetic energy across a spectral bandwidth that is defined by a ratio of at least 5:1. The system may also include a dielectric plate to which the antenna may be mounted. The dielectric plate may capable of deflecting projectiles. The antenna may be mounted to various locations on clothing. For example, the antenna may be mounted on an internal clothing layer or to an exterior surface of the article of clothing. Various articles of clothing may be used, for example, the article of clothing may be a vest.

In accordance with another aspect, a portable antenna system includes an antenna that is substantially defined by one or more portions that include electrically conductive self-similar extensions. The portable antenna system also includes a pouch, in which the antenna is contained. The pouch is also configured for mounting to a clothing surface.

In one embodiment, the system may further include a plate upon which the pouch is positioned such that the plate separates the antenna from the body of a person wearing clothing that includes the clothing surface. The self-similar extensions may include two or more angular bends. The system may also include a co-planar feed that is connected to the antenna for transmitting and/or receiving electromagnetic signals. Each self-similar extension may incorporate a fractal geometry. The pouch may include a layer of foam dielectric material or a layer of solid dielectric material. The pouch may include a fibrous dielectric material such as Tyvek™. The plate may include a projectile deflecting material.

In accordance with another aspect, a portable antenna system includes an antenna that is substantially defined one or more portions that include electrically conductive self-similar extensions. The system also includes a plate in which the antenna is mounted upon, and a garment in which the plate is attached to a clothing surface included in the garment.

In one embodiment, the plate may include a projectile deflecting material and/or a dielectric material. The garment may be a vest. The plate may be attached to a surface of the garment such that when worn, the antenna extends across the back of the person wearing the garment. Each self-similar extension may incorporate a fractal geometry. The antenna may transmit and/or receive electromagnetic energy across a spectral bandwidth that is defined by a ratio of at least 5:1.

Additional advantages and aspects of the present disclosure will become readily apparent to those skilled in the art from the following detailed description, wherein embodiments of the present invention are shown and described, simply by way of illustration of the best mode contemplated for practicing the present invention. As will be described, the present disclosure is capable of other and different embodiments, and its several details are susceptible of modification in various obvious respects, all without departing from the spirit of the present disclosure. Accordingly, the drawings and description are to be regarded as illustrative in nature, and not as limitative.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a diagrammatic view of a wideband antenna mounted to a garment.

FIG. **2** is a diagrammatic view of the wideband antenna shown in FIG. **1**.

FIG. **3** is a diagrammatic view of a pouch that holds the wideband antenna and may be mounted to the garment shown in FIG. **1**.

FIG. **4** is a diagrammatic view of wideband antenna embedded into a projectile deflecting plate that is mounted on a garment.

DETAILED DESCRIPTION OF THE EMBODIMENTS

Referring to FIG. **1**, an antenna **10** is mounted conformal to a surface of a garment. In particular, antenna **10** is mounted to the back of a vest **12**, however, in other arrangements the antenna **10** may be mounted to other types of garments such as shirts, coats, parkas, etc. By mounting antenna **10** to the back of vest **12**, a fully integrated antenna is provided for various applications such as combat wear for military personnel. In some arrangements antenna **10** may be incorporated into a military "flak" vest or other similar military clothing known in the art for protecting soldiers in hazardous situations. Typically a flak vest is produced from light-weight material and includes conducting regions formed from a metalized cloth. Such cloth may be formed of a copper coated polyester fabric that is commercially available from Flectron Metalized Materials of St. Louis, Mo. However, any materials known in the art of clothing design and tailoring may be used to produce vest **12**.

In this particular implementation, due to materials and production procedures, antenna **10** is opaque at visual wavelengths. However, in other implementations, antenna **10** may be substantially transparent at wavelengths in the visual portion of the electromagnetic spectrum. To mount antenna **10** conformal to vest **12**, the antenna predominately extends in two dimensions (i.e., length and width) and is relatively thin to provide flexibility in movement. Rather than mounting antenna **10** directly to the outer surface of vest **12**, the antenna may be embedded within one or more cloth layers of the vest. Some of these layers may be designed for particular capabilities, such as a bullet-proof layer or other types of projectile (e.g., flak) defection. For example, antenna **10** may be partially or fully embedded in one or more dielectric layer that are incorporated into the vest for bullet and/or flak deflection. A portion or all of this dielectric material may include one or more layers of foam or solid dielectric material. These layers of dielectric material may further be partially or fully embedded within another material. For example, antenna **10** may be embedded in a dielectric plate that is then wrapped around a fibrous dielectric material such as Tyvek®, which is produced by Dupont of Wilmington, Del.

Rather than incorporating antenna **10** into the clothing material of vest **12** (or other type of clothing article), the antenna may be incorporated into a pouch or other similar article capable of holding the antenna. By using a pouch, a person such as a soldier can position the antenna on various locations on his or her person. For example, a soldier may position the pouch on his chest or on his back to provide appropriate signal transmission and/or reception performance with other troops, a base, etc.

Along with being incorporated into an article of clothing or a pouch, antenna **10** is designed with a self-similar geometry that provides broad frequency coverage for signal transmission and/or reception. In general the self-similar shape is defined as a fractal geometry. Fractal geometry may be grouped into random fractals, which are also termed chaotic or Brownian fractals and include a random noise components, or deterministic fractals. Fractals typically have a statistical self-similarity at all resolutions and are generated by an infinitely recursive process. For example, a so-called Koch fractal may be produced with N iterations (e.g., N=1, N=2, etc.). One or more other types of fractal geometries may also be incorporated into the design of antenna **10**.

By incorporating the fractal geometry into electrically conductive and non-conductive portions of antenna **10**, the length and width of the conductive and non-conductive portions of the antenna is increased due to the nature of the fractal pattern. However, while the lengths and widths increase, the overall footprint area of antenna **10** is relatively small. By providing longer conductive paths, antenna **10** can perform over a broad frequency band. For example, the size reduction (relative to a wavelength) for the lowest frequency of operation approximately has a ratio of approximately 15:1 to 20:1.

Antenna **10** provides wideband frequency coverage for transmitting and/or receiving electromagnetic signals. For example, bandwidths ratios of 5:1 or larger may be supported by antenna **10**. For this lower ratio (i.e., 5:1) antenna **10** may perform at frequencies within a broad frequency band, for example, of approximately 3000 Mega Hertz (MHz) to 15,000 MHz. However, it should be appreciated that performance within other frequency bands may be achieved. Thus, antenna **10** is capable of transmitting and receiving electromagnetic signals over a broad frequency range.

Referring to FIG. **2**, antenna **10** is connected to a transceiver **14** over a conductor **16** (e.g., a cable, conducting trace, wire, etc.). By connecting to antenna **10**, transceiver **14** may send signals to the antenna for transmission or receive signals collected by the antenna. Typically to send and receive signals (and improve the gain of antenna **10**), transceiver **10** includes a low noise amplifier (LNA) and a power amplifier (PA). To connect conductor **16** to antenna **10**, a co-planar feed **18** is electrically connected to the antenna that also provides wideband performance. In some arrangements, a matching network is included in co-planar feed **18** to reduce signal dropouts (known as "suckouts") that are located within particular portions of the spectrum. Various techniques known to one skilled in the art of electronics and antenna system design may be implemented to connect connector **16** to antenna **10**. For example, an electrically conductive epoxy may be used to provide an adhesive connection with appropriate electrical conductivity. Additionally, in some embodiments other electromagnetic and electronic devices and components may be connected to co-planar feed **18**. For example, a power divider may be connected between conductor **16** and co-planar feed **18**.

In this exemplary fractal antenna design, antenna **10** includes an electrically conductive portion and a non-conductive portion. In particular, antenna **10** includes four sections **20**, **22**, **24**, **26** that include electrically conductive and non-conductive portions that implement a self-similar pattern (e.g., a fractal geometry). Both the conductive and non-conductive portions include extensions that include multiple angular bends to incorporate the self-similar pattern. In this example, each extension includes at least two angular bends. However, in other embodiments more angular bends may be incorporated to produce a similar fractal geometry or a different type of self-similar pattern.

In addition to incorporating a self-similar pattern into the conductive and non-conductive extensions, one or more self-similar patterns may be incorporated into the individual extensions. In this exemplary design, triangular holes are cut into two extensions **28** and **30** that are respectively included in section **22** and **26** of antenna **10**. Along with being distributed throughout each extension in a self-similar manner, each individual triangular hole may implement a fractal geometry.

Various types of conductive materials may be used to produce the electrically conductive portion (i.e., self-similar extensions) of antenna **10**. For example, various types of metallic material such as metallic tape, metallic paint, metallic ink or powder, metallic film, or other similar materials capable of conducting electricity may be selected. In this particular example, the electrically conductive portion of antenna **10** is produced from an electrically conductive coating that covers a non-conductive substrate. To produce the shape of the self-similar extensions, a laser or other type of cutting device may be used to ablate the conductive coating and from the non-conductive substrate.

By exposing portions of the non-conductive substrate, a boundary of the outer-most self-similar extensions is defined by a portion of the substrate. Additionally, exposed segments of the substrate define boundaries of the self-similar extensions. Various types of non-conductive materials may be used as a substrate to define the boundaries of the conductive portions of antenna **10**. For example, these materials may include insulators (e.g., air, etc.), dielectrics (e.g., glass, fiberglass, plastics, etc.), semiconductors, and other materials that impede the flow of electricity.

In some embodiments, the non-conductive portions of antenna **10** are produced from a high quality plastic or fiberglass that is structurally sturdy and may be processed (e.g., shaped) relatively quickly. Along with impeding current flow, the non-conductive material also typically provides structural support to the conductive portion of antenna **10**. To provide such support, the non-conductive materials may include materials typically used for support and/or re-enforce other materials. To protect antenna **10** (and provide structural support), a visually transparent (or semi-transparent) material may cover the conductive and non-conductive portions of the antenna. For example, both sides of antenna **10** may be covered by a transparent laminate that is applied with a thermal transfer. The electrically conductive portion and the non-conductive may also be cover by similar or dissimilar material. For example, one laminate may be used to cover the conductive portion of antenna **10** while another laminate is used to cover the non-conductive portion. These different laminates may be used to approximately match the optical appearance of both portions. Multiple layers of materials may also be used to cover the portions of antenna **10**. For example, one layer of laminate may be applied to the electrically-conductive portions of antenna **10** and two or more layers of laminate may be applied to the non-conductive portions to match the optical appearances of the entire antenna.

In this exemplary design, the four portions **20**-**26** are configured to provide a dipole response pattern for transmission and/or reception. Alternatively, other antenna designs may be implemented (e.g., a phased array design, etc.) independent or in combination with the dipole design provided in the figure. To expand the frequency coverage of antenna **10**, additional structure may be included in the antenna. For example, one or more conductors (e.g., conductive traces, wires, etc.) may be attached to some (or all) of the self-similar extensions. By including these conductive attachments, the frequency coverage of antenna may be significantly extended. For example, for this exemplary design, the frequency coverage may extend to relatively low frequencies.

Antenna **10** may be implemented into various types of antenna systems known to one skilled in the art of antenna design and antenna system design. In one scenario, antenna **10** may be used to transfer radio frequency (RF) signals among people such as military personnel in the field, various types of instillations (e.g., bases, etc.), and/or telecommunication equipment (e.g., wireless telephones, cellular telephones, satellites, etc.).

Along with wideband frequency coverage for broadband operations, by incorporating a fractal geometry into antenna **10** to increase conductive trace length and width, antenna losses are reduced. By reducing antenna loss, the output impedance of antenna **10** is held to a nearly constant value across the operating range of the antenna. For example, a 50-ohm output impedance may be provided by antenna **10** across the operational frequency band.

Referring to FIG. **3**, a pouch **32** is shown in which antenna **10** may be inserted. In this particular arrangement, antenna **10** is mounted to a plate **34** that provides structural support. By inserting antenna **10** in pouch **32**, the antenna may be positioned upon various locations of a person that is carrying the pouch. For example, pouch **32** may be attached to the front, back, or side of vest or other type of clothing worn over the torso. Along with wearing pouch **32** external to a piece of clothing or garment, the pouch may be worn under a garment or inserted into between clothing layers of a garment. As mentioned above, various types of material may be incorporated into the pouch. For example, pouch **32** may include one or more layers of foam or solid dielectric material. Fibrous material such as Tyvek™ may also be implemented to cover or wrap around antenna **10**. To attach pouch **32** to a garment of a piece of clothing, various techniques known in the art of clothing design and tailoring may be implemented. For example, Velcro™, straps, hooks, or other similar materials and/or mechanisms may implemented for attaching the pouch. In this exemplary design, one antenna (i.e., antenna **10**) is inserted into pouch **32**, however, in other implementation, a pouch may be produced that is capable of holding two or more antennas to increase directional coverage. Furthermore, by including electronic equipment such as a power divider in pouch **32**, signals may be split among the multiple antennas. Structural plate **34** may be produced from various materials, for example, the plate may be produced from one or more dielectric materials (e.g., ceramic). In addition to providing structural support, plate **34** may also increase the distance between antenna **10** and the body for the person (e.g., a soldier) that is carrying pouch **32**. For example, pouch **32** maybe positioned on the back of a person such that plate **34** provides a separation distance between antenna **10** and the person's back. This separation distance increases the electric distance between the person and antenna **10** and thereby reduces the interference effects caused by the person's body. By decreasing this interference, performance improves for antenna **10**. In this exemplary design, antenna **10** and plate **34** are inserted into pouch **32** that is positioned on a person's body (e.g., back, chest, etc.). However, in other designs plate **34** may be positioned without the need of pouch **32**.

Referring to FIG. **4**, antenna **10** is embedded in a structural plate **36** that is attached to the back of a vest **38**. Similar to plate **34** (shown in FIG. **4**), structural plate **36** also separates antenna **10** from the body of the person wearing vest **38**. By providing this separation, the performance of antenna **10** improves since the separation reduces the interference effects of the person's body. Also, by implementing various types of material into plate **36**, additionally capabilities may be provided. For example, projectile deflection materials known to one skilled in the art of armor design and personnel protection technology may be incorporated into plate **36**. Various types of bullet deflecting and/or flak deflecting materials may be incorporated into the exterior surface or inner layers of plate **36**.

A number of implementations have been described. Nevertheless, it will be understood that various modifications may be made. Accordingly, other implementations are within the scope of the following claims.

What is claimed is:

1. A portable antenna system comprising:

an antenna that includes (i) an electrically conductive portion including electrically conductive traces each including a fractal pattern based on an acute angle, and (ii) an electrically non-conductive portion that structurally supports the electrically conductive portion; and

an article of clothing, wherein the antenna is fixedly attached to a surface ofthe article of clothing such that electrically conductive traces extend across the surface of the article of clothing.

2. The portable antenna system of claim **1**, wherein the traces include two or more angular bends.

3. The portable antenna system of claim **1**, further comprising:

a co-planar feed connected to the antenna for transmitting and/or receiving electromagnetic signals through the antenna.

4. The portable antenna system of claim **1**, wherein the antenna is configured to transmit electromagnetic energy across a spectral bandwidth that is defined by a ratio of at least 5:1.

5. The portable antenna system of claim **1**, wherein the antenna is configured to receive electromagnetic energy across a spectral bandwidth that is defined by a ratio of at least 5:1.

6. The portable antenna system of claim **1**, further comprising:

a dielectric plate to which the antenna is mounted.

7. The portable antenna system of claim **6**, wherein the dielectric plate is capable of deflecting projectiles.

8. The portable antenna system of claim **1**, wherein the antenna is mounted on an internal clothing layer of the article of clothing.

9. The portable antenna system of claim **1**, wherein the antenna is mounted to an exterior surface of the article of clothing.

10. The portable antenna system of claim **1**, wherein the article of clothing is a vest.

[57] ABSTRACT

There is disclosed herein an electric machine or engine in which a rotor cage having an array of electromagnets is rotatable in an array of electromagnets, or fixed electromagnets are juxtaposed against movable ones. The coils of the electromagnets are connected in the discharge path of capacitors charged to relatively high voltage and discharged through the electromagnetic coils when selected rotor and stator elements are in alignment, or when the fixed electromagnets and movable electromagnets are juxtaposed. The discharge occurs across spark gaps disclosed in alignment with respect to the desired juxtaposition of the selected movable and stationary electromagnets. The capacitor discharges occur simultaneously through juxtaposed stationary movable electromagnets wound so that their respective cores are in magnetic repulsion polarity, thus resulting in the forced motion of movable electromagnetic elements away from the juxtaposed stationary electromagnetic elements at the discharge, thereby achieving motion. In an engine, the discharges occur successively across selected ones of the gaps to maintain continuous rotation. Capacitors are recharged between successive alignment positions of particular rotor and stator electromagnets of the engine.

FIG. 18.

PULSED CAPACITOR DISCHARGE ELECTRIC ENGINE

BACKGROUND OF THE INVENTION

1. Field of the Invention

There is no known engine or motor operated on the principle of the present invention, that a capacitor charged to a relatively high voltage from a low-voltage d-c source is discharged across a spark gap to provide current through motor drive coils in the discharge path, these being solenoids which generate motion by magnetic repulsion of juxtaposed pairs of cores. The solenoids are preferably configured in motor and stator assemblies to effect motion of the rotor element with respect to the stator.

The present invention utilizes this principle to provide a rotary motion machine or engine which can develop considerable torque through the magnetic repulsion action of rotor and stator cores wound with coils through which capacitors are discharged synchronously with the positioning of the rotor coils opposite particular stator coils. Similarly, a linear action can be achieved with a stationary electromagnet juxtaposed against a movable electromagnet and the movable electromagnet can perform work with a tool or piston attached thereto.

A novel control mechanism is associated with the rotor is the engine to position discharge elements appropriately to create the desired discharge through the electromagnet coils when the juxtaposed rotor and stator electromagnets are in alignment. The electromagnets in the stator and rotor are so arranged that the control mechanism can advance or retard the discharge points relative to rotor-stator positions for control of rotational speed.

The discharge overshoot or back e.m.f. from the collapsing fields in the coils from the capacitor discharge is used to energize external batteries for conservation of power. The recovered energy thus stored may be used to operate equipment associated with the engine or motive force producing device.

The engine or rotary electric machine of the invention is believed to operate on the principle of conservation of energy, in that once rotation is achieved, current is needed only at the instant of a capacitor discharge in order to advance the rotor. The rotor moves to the next discharge point on the inertia of the repulsion action. The capacitor is recharged during the interval and stores the energy until discharge at the next rotor-stator coil coincidence. Thus, the new engine produces torque and stores the excess energy for subsequent use.

In a linear motion device according to the invention, only a single pulse discharge is needed to perform work.

The applications of the engine include use as an electric automotive engine which is economical and which can regenerate a part of the energy consumed to provide power for other loads in the automotive electric vehicle. As a linear actuator an economical use of power is possible because each stroke will result from a single discharge pulse of a capacitor through a coil.

2. Prior Art

Heretofore, electric engines or motors have operated on the principle that a conductor carrying a current in a magnetic field tends to move perpendicularly to that field; the electromagnetic torque developed by an armature or rotating portion of the motor is proportional to the magnetic flux in the stationary field and to the armature current.

In direct current motors the field is created by current through two or more field coils disposed in opposing magnetic relationship in the motor casing, while current through a rotatable armature positioned in the field is alternatingly reversed in polarity to provide continuous motion. The polarity reversing mechanism is a commutator. Some d-c motors have their field windings electrically in parallel with the rotor armature winding and are called "shunt-wound" motors. Other d-c motors have field and armature windings connected in series. In both series and shunt motors commutators are used for reversing the magnetic polarity of the armature to maintain rotation within the field.

A third type of d-c motor utilizes a permanent magnet field so that the operating current passes only through the armature winding. Such motors also use polarity reversing commutators to maintain direction of rotation. Reversal of direction of motion is effected by reversing the polarity of applied d-c potential.

Control of speed of d-c motors is accomplished basically by decrease or increase of magnetic field flux or the current through the armature. Either or both of these effects can be accomplished by raising or lowering the applied potential. In shunt motors, a series resistance may be varied to produce speed changes. In a permanent magnet motor or series motor, speed variation is best accomplished by voltage variation with a variable resistance in series with the motor d-c supply.

In alternating current motors, as is well known, a rotating magnetic field is created in the stator, and the rotor may be wound with as many poles as there are in the stator, with terminals connected with slip rings, or the rotor may consist of solid bars shorted by rings on each end to form a "squirrel cage" configuration. The speed of an a-c motor depends on the frequency of the applied a-c energy, if the motor is synchronous.

"Universal" motors are operable on either a-c or d-c energy.

In stepping motors, a rotor is moved from one pole to the next adjacent pole with each application of current, the rotor remaining at that position until a next application of current. This is accomplished by switching the current on and off or by pulsing the current. Examples of stepping motors are described in U.S. Pat. No. 3,467,902 to Shimizu, et al., U.S. Pat. No. 3,462,667 to Jackson, and U.S. Pat. No. 3,599,069 to Welch.

Operation of the a-c and d-c motors described above involves the consumption of substantial electric current. These motors can generate electric current when driven externally by a mechanical force. External energy to rotate the generator rotors can be provided by hydroelectric and steam sources or by other electric motors. In some of these systems, a d-c motor source drives an a-c generator for conversion of d-c energy to a-c energy or a d-c motor may drive a d-c generator which delivers a higher voltage than the source.

An extensive prior art search by the applicant uncovered no capacitor-discharge-operated motor resembling that of the present invention. All motors of the patents located in the search employed direct electrical connection between coils and electric power sources. Where selective switching is involved, semiconductor devices are employed, such as silicon-controlled rectifiers. Capacitors are used only for starting and phasing purposes, and not for basic motor operation from the discharge thereof, as in this invention.

SUMMARY OF THE INVENTION

This invention relates to electric motors or engines, and more particularly to a new electric machine including electromagnetic poles in a stator configuration and electromagnetic poles in a rotor configuration wherein in one form thereof the rotor is rotatable within the stator configuration and where both are energized by capacitor discharges through rotor and stator electromagnets at the instant of the alignment of a rotor electromagnet with a stator electromagnet. The rotor electromagnet is repelled from the stator electromagnet by the discharge of the capacitor through the coils of both the stator and rotor electromagnets at the same instant.

In an exemplary rotary engine according to this invention, rotor electromagnets may be disposed 120° apart on a central shaft and major stator electromagnets may be disposed 40° apart in the motor housing about the stator periphery. Other combinations of rotor elements and stator elements may be utilized to increase torque or rotation rate.

In another form, a second electromagnet is positioned to one side of each of the major stator electromagnets on a center line 13⅓° from the center line of the stator magnet, and these are excited in a predetermined pattern or sequence. Similarly to one side of each major rotor electromagnet is a second electromagnet spaced on a 13⅓° center line from the major rotor electromagnet. Electromagnets in both the rotor and stator assemblies are identical, the individual electromagnets of each being aligned axially and the coils of each being wired so that each rotor electromagnetic pole will have the same magnetic polarity as the electromagnet in the stator with which it is aligned and which it is confronting at the time of discharge of the capacitor.

Charging of the discharge capacitor or capacitors is accomplished by an electrical switching circuit wherein electrical energy from a battery or other source of d-c potential may be applied in alternating polarity to ignition coils or other voltage step-up arrangements from which a high voltage d-c potential is derived through rectification by diodes.

The capacitor charging circuit comprises a pair of high frequency switchers which feed respective automotive-type ignition coils employed as step-up transformers. The "secondary" of each of the ignition coils provides a high voltage square wave to a half-wave rectifier to generate a high voltage output pulse of d-c energy with each switching alternation of the high frequency switcher. Only one polarity is used so that a unidirectional pulse is applied to the capacitor bank being charged.

Successive unidirectional pulses are accumulated on the capacitor or capacitor bank until discharged. Discharge of the bank of capacitors occurs across a spark gap by arc-over. The gap spacing determines the voltage at which discharge or arc-over occurs. An array of gaps is created by fixed elements in the engine housing and moving elements positioned on the rotor shaft. At the instant when the moving gap elements are positioned opposite fixed elements during the rotor rotation, a discharge occurs through the coils of the aligned rotor and stator electromagnets to produce the repulsion action between the stator and rotor electromagnet cores.

A plurality of fixed gap elements are arrayed in the motor housing to correspond to the locations of the stator electromagnets in the housing. The rotor gap elements correspond to the positions of the rotor electromagnets on the rotor so that at the instant of correct alignment of the gaps the capacitors are discharged to produce the necessary current through the stator and rotor coils to cause the electromagnets to repel one another.

The charging circuits are arranged in pairs, and are such that the discharge occurs through both rotor and stator windings of the electromagnets, which are opposite one another when the spark gap elements are aligned and arc-over.

The speed of the rotor can be changed by means of a clutch mechanism associated with the rotor. The clutch shifts the positions of the rotor gap elements so that the discharge will energize the stator coils in a manner to advance or retard the time of discharge with respect to the normal rotor/stator alignment positions. The discharge through the rotor and stator then occurs when the rotor has passed the stator 6⅔° for speed advance.

By causing the discharge to occur when the rotor position is approaching the stator, the repulsion pulse occurs 6⅔° before the alignment position of the rotor and stator electromagnets, thus slowing the speed.

The clutch mechanism for aligning capacitor discharge gaps for discharge is described as a control head. It may be likened to a firing control mechanism in an automotive combustion engine in that it "fires" the electromagnets and provides a return of any discharge overshoot potential back to the battery or other energy source.

The action of the control head is extremely fast. From the foregoing description, it can be anticipated that an increase in the speed or a decrease in speed of rotation can occur within the period in which the rotor electromagnet moves between any pair of adjacently located electromagnets in the stator assembly, which are 40° apart in the exemplary engine according to the invention. Thus, speed changes can be effected in a maximum of one-ninth of a revolution.

The rotor speed-changing action of the control head and its structure are believed to be further novel features of the invention, in that they maintain normal 120° firing positions during uniform speed or rotation conditions, but shift to ±6⅔° longer or shorter intervals for speed change by the novel shift mechanism in the rotor clutch assembly.

Accordingly, the preferred embodiment of this invention is an electric rotary engine wherein motor torque is developed by discharge of high potential from a bank of capacitors through stator and rotor electromagnet coils when the electromagnets are in alignment. The capacitors are charged from batteries by a switching mechanism, and are discharged across spark gaps set to achieve the discharge of the capacitor charge voltage through the electromagnetic coils when the gaps and predetermined rotor and stator electromagnet pairs are in alignment.

Exemplary embodiments of the invention are herein illustrated and described. These exemplary illustrations and description should not be construed as limiting the invention to the embodiments shown, because those skilled in the arts appertaining to the invention may conceive of other embodiments in the light of the description within the ambit of the appended claims.

DESCRIPTION OF THE PREFERRED EMBODIMENT

As hereinbefore mentioned, the basic principle of operation of the engine of the invention is the discharge of a capacitor, across a spark gap through an inductor. When a pair of inductors is used, and the respective magnetic cores thereof are arranged opposite and another in magnetic polarity repulsion relation, the discharge through them causes the cores to repel each other with considerable force.

Referring to the electrical schematic diagram of FIG. **1**, a battery **10** energizes a pulse-producing vibrator mechanism **16**, which may be of the magnetic type incorporating an armature **15** moving between contacts **13** and **14**, or of the transistor type (not shown) with which a high frequency bipolar pulsed output is produced in primary **17** of transformer **20**. The pulse amplitude is stepped-up in secondary **19** of transformer **20**. Wave form **19***a* represents the bidirectional or bipolar pulsed output. A diode rectifier **21** produces a unidirectional pulse train, as indicated at **21***a*, to charge capacitor **26**. A delay coil **23** is connected in series with the unipolar pulsed output to capacitor **26**. Successive unidirectional pulses of wave **21***a* charge capacitor **26** to a high level, as indicated at **26***a*, until the voltage amplitude at point A reaches the breakdown potential of spark gap **30**. At the breakdown of spark gap **30**, capacitor **26** discharges across the arc created through the inductor coil **28**. A current pulse is produced which magnetizes core **28***a*. Simultaneously, another substantially identical charging system **32** produces a discharge through inductor **27** across spark gap **29** to magnetize core **27***a*. Cores **28***a*, **27***a* are wound with coils **28**, **27** so that their magnetic polarities are the same. As the cores **27***a*, **28***a* confront one another, they tend to fly apart when the discharge occurs through coils **27** and **28** because of repulsion of identical magnetic poles, as indicated by arrow **31**. If core **28***a* is fixed or stationary and core **27***a* is movable, then core **27***a* may have tools **33** attached to it to perform work when the capacitor discharges.

Referring to FIGS. **1** and **2**, a d-c electrical source or battery **10** energizes pulsators **36** (including at least two vibrators **16** as previously described) when switch **11** between the battery **10** and pulsator **36** is closed, to apply relatively high frequency pulses to the primaries of transformers **20**. The secondaries of transformers **20** are step-up windings which apply bipolar pulses, such as pulses **19***a* (FIG. **1**) to the diodes in converter **38**. The rectified unidirectional pulsating output of each of the diodes in converter **38** is passed through delay coils **23**, **24**, thus forming a harness **37** wound about the case of the engine, as hereinafter described, which is believed to provide a static floating flux field. The outputs from delay lines **37** drive respective capacitors in banks **39** to charge the capacitors therein to a relatively high charge potential. A programmer and rotor and stator magnet control array **40**, **41**, **42** is formed by spark gaps positioned, as hereinafter described, so that at predetermined positions of the rotor during rotation of the engine, as hereinafter described, selected capacitors of capacitor banks **39** will discharge across the spark gaps through the rotor and stator electromagnets **43**, **44**. The converters **38**, magnetic harness **37**, capacitor banks **39**, programmer **40**, and controls **41**, **42** from a series circuit path across the secondaries of transformers **20** to the ground, or point of reference potential, **45**. The capacitor banks **39** are discharged across the spark gaps of programmer **40** (the rotor and stator magnet controls **41**, **42**). The discharge occurs through the coils of stator and rotor electromagnets **43**, **44** to ground **45**. Stator and rotor electromagnets are similar to those shown at **27**, **27***a*, **28**, **28***a* in FIG. **1**.

The discharge through the coils of stator and rotor electromagnets **43**, **44** is accompanied by a discharge overshoot or return pulse, the output of which is applied in an appropriate polarity to a secondary battery **10***a* to store this excess energy. The overshoot pulse returns to battery **10***a* because after discharge the only path open is that to battery **10***a*, since the gaps in **40**, 41 and **42** have broken down, because the capacitors in banks **39** are discharged and have not yet recovered the high voltage charge from the high frequency pulsers **36** and converter rectifier units **38.**

In the event of a misfire in the programmer control circuits **40, 41, 42,** the capacitors are discharged through a rotor safety discharge circuit **46** and returned to batteries **10–10***a*, adding to their capacity. The circuit **46** is connected between the capacitor banks **39** and batteries **10, 10***a*.

Referring to FIG. **3**, a motor or engine **49** according to the present invention is shown connected with an automotive transmission **48.** The transmission **48** represents one of many forms of loads to which the engine may be applied. A motor housing **50** encases the operating mechanism hereinafter described. The programmer **40** is axially mounted at one end of this housing. Through apertures **51, 52** a belt **53** couples to a pulley **57** (not shown in this view) and to an alternator **54** attached to housing **50.** A pulley **55** on the alternator has two grooves, one for belt **53** to the drive pulley **58** on the shaft (not shown) of the engine **49,** and the other for a belt **58** coupled to a pulley **59** on a pump **60** attached to housing **50.** A terminal box **61** on the housing interconnects means between the battery assembly **62** and motor **49** via cables **63** and **64.**

An intake **65** for air is coupled to pump **60** via piping **68, 69** and from pump **60** via tubing or piping **66, 70** to the interior of housing **50** via coupling flanges **67** and **71.** The air flow tends to cool the engine, and the air may preferably be maintained at a constant temperature and humidity so that a constant spark gap discharge condition is maintained. A clutch mechanism **80** is provided on programmer **40.**

Referring to FIGS. **4, 5** and **9,** rotor **81** has spider assemblies **83, 84** with three electromagnet coil assembly sets mounted thereon, two of which are shown in FIG. **4,** on **85** at **85***a* and **85***b*, and on **86** at **86***a* and **86***b*. One of the third electromagnet coil assemblies, designated **87***a*, is shown in FIG. **5**, viewed from the shaft end. As more clearly shown in the perspective view of FIG. **8,** a third spider assembly **88** provides added rigidity and a central support for the rotor mechanism on shaft **81.**

The electromagnet sets **85***a* and **85***b*, 86*a* and **86***b*, **87***a* and **87***b*, disposed on rotor **81** and spiders **83, 84,** and **88** each comprise pairs of front units **85***a*, 86*a*, 87*a* and pairs of rear units **85***b*, 86*b*, 87*b*. Each pair consists of a major electromagnet and a minor electromagnet, as hereinafter described, which are embedded in an insulating material **90,** which insulates the electromagnet coil assemblies from one another and secures the electromagnets rigidly in place on the spider/rotor cage **81,** 83, 84, 88.

The interior wall **98** of housing **50** is coated with an electrically insulating material **99** in which are embedded electromagnet coils, as hereinafter described, and the interiors of end plates **100, 101** of the housing **50.** On the insulating surface **98** of housing **50** is mounted a series of stator electromagnet pairs **104***a*, identical with electromagnet pairs **85***a*, 86*a*, 87*a*, etc. Electromagnet pairs such as **104***a* or **105***a* are disposed every 40° about the interior of housing **50** to form a stator which cooperates with the rotor **81–88.** An air gap **110** of very close tolerance is defined between the rotor and stator electromagnets, and air from pump **65** flows through this gap.

As shown in FIG. **8,** the electromagnet assemblies, such as **85** through **87,** of the rotor and magnet assemblies, such as **104***a* in the stator are so embedded in their respective insulative plastic carriers (rotor and stator) that they are smoothly rounded in a concave contour for the stator, and in a convex contour on the rotor to permit smooth and continuous rotation of rotor **81** in stator housing **50.** The air gap **110** is uniform at all positions of any rotor element within the stator assembly, as is clearly shown in FIG. **16.**

The rotor **81** and spiders **83, 84, 88** are rigidly mounted on a shaft **111** journaled in bearing assemblies **112, 113** which are of conventional type, for easy rotation of the rotor on shaft **111** within housing **50.**

Around the central outer surface of housing **50** are wound a number of turns of wire **23, 24** to provide a static flux coil **114** as hereinbefore described, which is a delay line, as previously described.

FIGS. **5, 6, 7** and **9** are cross-sectional views of the rotor assembly **81–88,** arranged to show the positioning and alignment of the rotor and stator electromagnet coil assemblies at successive stages of the rotation of rotor **81–88** through a portion of a cycle of operation thereof. For example, in FIG. **5** the rotor assembly **81–88** is shown so positioned that a minor rotor electromagnet assembly **91** is aligned with a minor stator electromagnet assembly **117.**

As shown in further detail in FIG. **16,** minor electromagnet assembly **117** consists of an iron core **118,** grooved so that there may be wound thereabout a coil of wire **119.** Core **118** is the same in stator electromagnet **117** as it is in rotor electromagnet **91.**

As a position 13⅓° to the right of rotor electromagnet **91,** as viewed in FIGS. **5** and **16,** there is a second or major rotor electromagnet **121** which has a winding **123** about its core **122.** The electromagnets **91, 121** are the pair **85***a* of FIGS. **4** and **8.**

At a position 13⅓° to the left of stator electromagnet **117,** as viewed in FIG. **5,** there is a second or major stator electromagnet **120** whose core **122** is of the same configuration as core **122** of rotor electromagnet **121.** A winding **123** about core **122** of electromagnet **120** is of the same character as winding **123** on electromagnet **121.**

Electromagnet assembly pair **85***a* on the rotor is identical in configuration with that of the electromagnet stator assembly pair **104***a* except for the position reversal of the elements **117–120** and **91–121** of the respective pairs.

There are nine pairs of electromagnets **120–117** (**104***a*) disposed at 40° intervals about the interior of housing **50.** The center line of core **122** of electromagnet **120** is positioned 13⅓° to the left of the center line of the core **118** of electromagnet **117.** Three pairs of electromagnets **85***a*, 86*a*, 87*a* are provided on rotor assembly **81–88** as shown in FIG. **5.**

Other combinations are possible, but the number of electromagnets in the rotor should always be an integral fraction of the number of electromagnets in the stator. As shown in FIG. **8,** for the rotor assembly **85***a*, 85*b*, there are three of each of the front and back pairs of electromagnetic assemblies. Similarly, as shown in FIGS. 4 and **8,** there are nine front and back pairs of electromagnets in the stator such as **104***a* and **104***b*.

In order to best understand the operation of the rotor **81–88** rotating within the stator housing **50** of an engine according to this invention, the positions of rotor electromagnets **91** and stator electromagnets **117** are initially exactly in line at the 13⅓° peripheral starting position marked on the vertical center line of FIG. **5.** The winding direction of the coils of these magnets is such that a d-c current through the coils **119** will produce a particular identical magnetic polarity on each of the juxtaposed surfaces **125** of magnet **117,** and **126** of magnet **91,** (FIG. **5**). FIGS. **16** and **6** illustrate the next step in the motion wherein the two major electromagnets, **120** in the stator and **121** in the rotor, are in alignment.

When the d-c discharges from the appropriate capacitors in banks **39** occur simultaneously across spark gaps through the coils **119** of electromagnets **117** and **91,** at the instant of their alignment, their cores **118** will repel one another to cause rotor assembly **81–88** to rotate clockwise in the direction indicated by arrow **127.** The system does not move in the reverse direction because it has been started in the clockwise direction by the alternator motor **54** shown in FIG. **3,** or by some other starter means. If started counterclockwise, the rotor will continue to move counterclockwise.

As hereinbefore noted, the discharge of any capacitor occurs over a very short interval across its associated spark gap, and the resulting magnetic repulsion action imparts motion to the rotor. The discharge event occurs when electromagnets **117** and **91** are in alignment. As shown in FIG. **5,** rotor electromagnet **91*a*** is aligned with stator electromagnet **117*c*,** and rotor electromagnet **91*b*** is aligned with stator electromagnet **117*e*** at the same time that similar electromagnets **117** and **91** are aligned. A discharge occurs through all six of these electromagnets simultaneously (that is, **117,** 91; **117*c*,** 91*a*, 117*e* and **91*b***). A capacitor and a spark gap are required for each coil of each electromagnet. Where, as in the assembly shown in FIG. **8,** front and back pairs are used, both the axial in-line front and back coils are energized simultaneously by the discharge from a single capacitor or from a bank of paralleled capacitors such as **25, 26** (FIG. **1**). Although FIGS. **4** and **8** indicate the use of front and back electromagnets, it should be evident that only a single electromagnet in any stator position and a corresponding single electromagnet in the rotor position, may be utilized to accomplish the repulsion action of the rotor with respect to the stator. As stated, each electromagnet requires a discharge from a single capacitor or capacitor bank across a spark gap for it to be energized, and the magnetic polarity of the juxtaposed magnetic core faces must be the same, in order to effect the repulsive action to produce the rotary motion.

Referring to FIGS. **5** and **6,** the repulsion action causes the rotor to move 13⅓° clockwise, while electromagnets **91, 91*a*** and **91*b*** move away from electromagnets **117, 117*c*** and **117*e*** to bring electromagnets **121, 121*a*** and **121*b*** into respective alignment with electromagnets **120*a*,** 120*d* and **120*f*.** At this time, a capacitor discharge across a spark-gap into their coils **123** occurs, thus moving the rotor. Another 13⅓° ahead, as shown in FIG. **7,** major electromagnets **121, 121*a*** and **121*b*** come into alignment with minor electromagnets **117*a*,** 117*d* and **117*f*,** at which time a discharge occurs to repeat the repulsion action, this action continuing as long as d-c power is applied to the system to charge the capacitors in the capacitor banks.

FIG. **18** further illustrates the sequencing of the capacitor discharges across appropriate spark gap terminal pairs. Nine single stator coils and three single rotor coils are shown with their respective interconnections with the spark gaps and capacitors with which they are associated for discharge. When the appropriate spark gap terminals are aligned, at the points in the positioning of the rotor assembly for most effective repulsion action of juxtaposed electromagnet cores, the discharge of the appropriate charged capacitors across the associated spark gap occurs through the respective coils. The capacitors are discharged in sets of three through sets of three coils at each discharge position, as the rotor moves through the rotor positions. In FIG. **18,** the rotor electromagnets are positioned linearly, rather than on a circular base, to show the electrical action of an electric engine according to the invention. These motor electromagnets **201, 202,** and **203** are aligned with stator electromagnets **213, 214** and **215** at 0°, 120° and 450° respectively. The stator electromagnets are correspondingly shown in a linear schematic as if rolled out of the stator assembly and laid side by side. For clarity of description, the capacitors associated with the rotor operation **207, 208, 209** and **246, 247,** 248, 249, 282 and **283** are arranged in vertical alignment with the respective positions of the rotor coils **201, 202, 203** as they move from left to right, this corresponding to clockwise rotation of the rotor. The stator coils **213, 214, 215, 260, 261, 262, 263, 264, 265,** 266, etc. and capacitor combinations are arranged side by side, again to facilitate description.

An insulative disc **236** (shown in FIG. **17** as a disc, but opened out linearly in FIG. **18**) has mounted thereon three gap terminal blocks **222, 225** and **228.** Each block is rectangularly U-shaped, and each interconnects two terminals with the base of the U. Block **222** has terminals **222*a*** and **222*b*,** block **225** has terminals **225*a*** and **225*b*,** and block **228** has terminals **228*c*** and **228*d*.** When insulative disc **230** is part of the rotor, as indicated by mechanical linkage **290,** it can be seen that terminal U **222** creates a pair of gaps with gap terminals **223** and **224,** respectively. Thus, when the voltage on capacitor **216** from charging circuit **219** is of a value which will arc over the air spaces between **222*a*** and **223,** and between **222*b*** and **224,** the capacitor **216** will discharge into the coil of electromagnet **213** to ground. Similarly gap terminal U **225** forms a dual spark gap with gap terminals **226** and **227** to result in arc-over when the voltage on capacitor **217,** charged by charging circuit **220,** discharges into the coil of electromagnet **214.** Also, U-gap terminal **228** with terminals **228*c*** and **228*d*,** creates a spark gap with terminals **229** and **230** to discharge capacitor **218,** charged by charging circuit **221,** into coil **215.** At the same time, rotor coils, **201, 202** and **203** across gaps **201*a*–204,** 202*b*–**205** and **203*c*–206** each receives a discharge from respective capacitors **207, 208,** and **209.**

When the electromagnet coils **213, 214, 215** and **201, 202, 203** are energized, the repulsion action causes the rotor assembly to move to position **2** where a new simultaneous group of discharges occurs into rotor coils **201, 202,** and **203** from capacitors **246, 248,** and **282** across gaps **201*a*–240, 202*b*–242** and **203*c*–244.** Simultaneously, because gap-U-elements **222, 225** and **228** have also moved to position **2** with the rotor assembly, capacitor **261** is discharged through electromagnet coil **260,** capacitor **265** is discharged through electromagnet coil **264,** and capacitor **269** is discharged through electromagnet coil **268** in alignment with position 2 of the rotor electromagnet coils, thus to cause the rotor electromagnets to move to position 3 where the discharge pattern is repeated now with capacitors **247, 249** and **283** discharging through the rotor electromagnet coils **201, 202, 203,** and the capacitors **263, 267** and **281** discharging respectively through stator electromagnet coils **262, 266** and **280.**

After each discharge the charging circuits **219–221** and **272–277** for the stator capacitors, and **210–212** and **284–289** for the rotor capacitors, are operated continuously from a battery source, as described earlier with reference to FIG. **1,** to constantly recharge the capacitors to which each is connected. Those versed in the art will appreciate that, as each capacitor discharges across an associated spark gap, the resulting drop in potential across the gap renders the gap an open circuit until such time as the capacitor can recharge to the arc-over level of the gap. This recharge to a discharge potential occurs before a rotor element arrives at the next position in question.

The mechanical schematic diagram of FIG. **17** further clarifies the operation of the spark-gap discharge programming system. A forward disc **236** of an electrically insulative material, has thereon the set of U-shaped gap terminal connectors previously described. These are positioned at 0°, 120° and 240° respectively. In FIG. **17,** schematic representations of the position of the coil and capacitor arrangements at the start of a cycle are shown to correspond to the description hereinabove with reference to FIG. **18.** Accordingly, the coil and capacitor combinations **213**/216, 214/217, and **215**/218 are shown connected with their gap terminals, respectively, **223**/224, 226/227 and **229**/230. On the rotor coil and capacitor connection three separate discs **291, 292** and **293** are shown, each with a single gap terminal. The discs **291–293** are rotated so as to position their respective gap terminals **201***a*, 202*b* and **203***c* at 120° increments, with the 0° position corresponding to the 0° position of U-gap terminal **222** on disc **230.**

Representative gap terminals are shown about the peripheries of discs **230, 291–293** to clearly indicate how, as the discs turn in unison, the gap alignments correspond so that three rotor coil/capacitor positions always line up with three stator coil/capacitors at 120° intervals about the rotary path, producing an alignment every 40°, there being nine stator coils. Thus there are three simultaneous discharges into stator coils and three into rotor coils at each 40° position. Nine positions displaced 40° apart provide a total of 27 discharge points for capacitors into the rotor coils and 27 discharge points for capacitors into the stator coils in one revolution.

It will be understood that, as illustrated in FIGS. **17** and **18,** nine individual electromagnet coils are shown in the stator and three in the rotor, in order to show in its simplest form how the three rotor electromagnets are stepped forward from alignment with three of the stator electromagnets, when the appropriate spark gaps are in alignment, to effect the discharge of capacitors through juxtaposed pairs of rotor/stator electromagnets. The repulsion moves the rotor electromagnet from the stator electromagnet to the next alignment position advanced at an arc of 40° from the preceding alignment position. In the interval until another rotor electromagnet, 120° removed, is aligned with the stator electromagnet that had just been excited, the associated capacitor is recharged to a potential which will cause the spark gap to break down to produce another discharge of this capacitor on the next revolution. Thus the rotor moves from one position to the next, with capacitor discharges occurring each 40° of rotation, a total of nine per revolution. It should be obvious that, with other rotor/stator combinations, the number of electromagnet coincidences and spark-gap discharges will vary. For example, with the coil pairs shown in FIGS. **4** through **8,** a total of 27 discharges will occur. Although there are 18 stator electromagnets and three rotor electromagnets, the discharge pattern is determined by the specific spark gap arrangement.

The rotor/stator configuration of FIGS. **5** and **8,** involving the major and minor pairs of electromagnets such as **85***a* and **104***a* (the terms "minor" and "major" referring to the difference in size of the elements), include nine pairs of electromagnets in the stator, such as **104***a*, with three electromagnet pairs of the rotor, such as **85***a*. Because of the 13⅓° separation between the major and minor electromagnets in the rotor pair **85***a*, with the same separation of minor and major electromagnets of the stator pair **104***a*, the sequence of rotation and discharge described above, with respect to the illustrative example of FIG. **5,** involves the following:

1. A minor element **117** of stator pair **104***a* is aligned with the minor element **91** of rotor pair **85***a*. On the discharge, this moves the rotor ahead 13⅓°.
2. The major rotor element **122** of the pair **85***a* now is aligned with the major stator element **120***b* of the next stator electromagnet pair, in the stator array as shown in FIG. **6.** On the discharge, the rotor moves ahead 13⅓°.
3. This brings the minor rotor electromagnet **91** into alignment with the major stator electromagnet **120***b* of pair **104***d*, and the major electromagnet **122** (just discharged) of pair **85***a* into alignment with minor electromagnet **117***b* of pair **104***d*, and the rotor spark gap ements into alignment with a different position of gap elements connected with capacitors not discharged in the previous position of the rotor. It should be remembered at this point that it is the positioning of a rotatable spark gap array, similar to that illustrated in FIGS. **17** and **18,** which controls the time of discharge of capacitors connected to these gap terminals. Therefore, any electromagnet can be energized twice successively from separate capacitors as the rotor brings appropriate gap terminals into alignment with the coil terminals of a particular electromagnet.

Thus, although major electromagnet **120***b* of pair **104***d* has just been energized as described above, it can now be energized again along with minor rotor electromagnet **91** in step **3,** because the rotor moved to a new set of terminals of the spark gap arrays connected with capacitors not yet discharged. These capacitors now discharge through rotor electromagnet **91** and stator electromagnet **120***b*, causing rotor to move ahead another 13⅓°, thus again aligning two minor electromagnets again, these being **117***b* of stator pair **104***d* and **91** of rotor pair **85***a*. The rotor has now moved 40° since step **1** above. The sequence is repeated, and it is to be noted that at each 13⅓° step, the discharges rotate the rotor another 13⅓°. There are 27 steps per revolution with nine stator coil pairs. The discharge sequence is not uniform, as is shown in Table I. In the stator, three major electromagnets 120° apart are energized twice in sequence followed by a hiatus of one step while three minor electromagnets of the stator, 120° apart, are energized during the hiatus. In the rotor the major electromagnets are energized during a hiatus step following two minor electromagnet energization steps. A total of 27 energizations are thus accomplished in the nine pairs of coils of the stator.

In Table I, the leftmost column depicts the location of each rotor arm **85, 86, 87** at an arbitrarily selected step No. **1** position. For example, in step **1** rotor arm **85** has a minor stator and minor rotor electromagnet in alignment for capacitors to discharge through them simultaneously at the 13⅓° position.

TABLE I

CAPACITOR DISCHARGE SEQUENCE FOR ONE REVOLUTION OF ROTOR IN SYSTEM OF FIGS. 5 AND 8

Step No. Rotor Arm				Rotor Electromagnet		Stator Electromagnet	
87	85	86	Rotor Angle	Minor	Major	Minor	Major
10	1	19	13 1/3°	x		x	
11	2	20	26 2/3°		x		x
12	3	21	40°	x			x
13	4	22	53 1/3°	x		x	
14	5	23	66 2/3°		x		x
15	6	24	80°	x			x
16	7	25	93 1/3°	x		x	
17	8	26	106 2/3°		x		x
18	9	27	120°	x			x
19	10	1	133 1/3°	x		x	
20	11	2	146 2/3°		x		x
21	12	3	160°	x			x
22	13	4	173 1/3°	x		x	
23	14	5	186 2/3°		x		x
24	15	6	200°	x			x
25	16	7	213 1/3°	x		x	
26	17	8	226 2/3°		x		x
27	18	9	240°	x			x
1	19	10	253 1/3°	x		x	
2	20	11	266 2/3°		x		x
3	21	12	280°	x			x
4	22	13	293 1/3°	x		x	
5	23	14	306 2/3°		x		x
6	24	15	320°	x			x
7	25	16	333 1/3°	x		x	
8	26	17	346 2/3°		x		x
9	27	18	360°	x			x

Similarly, in step **1** rotor arm **86** is at the 133⅓° position with a minor rotor and minor stator electromagnet in alignment for discharge. Simultaneously, rotor arm **87** is at the 253⅓° position with a minor rotor and minor stator in alignment for capacitor discharge therethrough. The other steps of the sequence are apparent from Table I, for each position of the three rotor arms at any step and the juxtapositions of respective stator and rotor electromagnet elements at that position.

In the simplified motor arrangement shown in schematic form in FIG. **18**, with single electromagnet configuration the alignment is uniform and the discharge sequences follow sequentially.

As hereinbefore mentioned, a change in speed is effected by displacing the stator spark gap terminals on the rotor (shown at **236** in FIGS. **17** and **18**) either counter-clockwise or clockwise 6⅔° so that the discharge position of the stator electromagnets is displaced 6⅔° either clockwise or counter-clockwise of a rotor electromagnet at the time of discharge. Referring to FIGS. **11** to **15**, the simultaneous discharge of selected capacitors into the electromagnets so displaced results in a deceleration at the time the rotor electromagnet is just approaching the associated stator, or an acceleration if the rotor electromagnet is just leaving its associated stator electromagnet. In each event, there is a repulsive reaction between the stator and rotor electromagnets, so that if the rotor is approaching the stator, there is a slow-down and if the rotor is receding from the stator there is a speed-up.

Referring to FIG. **11**, clutch mechanism **304** about shaft **111** is operated electromagnetically in conventional manner to displace the spark-gap mechanism **236** which is operated normally in appropriate matching alignment with the rotor spark-gap discs **291, 292,** 293. Clutch **304** has a fixed drive element **311** containing an electromagnetic drive coil (not shown) and a motor element **310** which, when the electromagnetic drive coil is energized, can be operated by a direct current. The operation of motor element **310** brings into operation spark gap elements **224*r***, 223*r* or **223*f***, 224*f* of the system shown in FIGS. **4, 5** and **8**, as illustrated in FIG. **19.**

The fixed stator coil spark gap terminal pairs **223,** 224 and **266, 267** are arrayed about a cylindrical frame **322** which is fabricated in insulative material. In the illustrative example of FIGS. **17** and **18**, there are nine such spark gap terminal pairs about the periphery of cylinder frame **324.** In the engine of FIGS. **4** to **8**, a total of 27 such spark gap pairs are involved. In addition, although not shown in the drawing, there are also pairs of terminals, such as **223*r*** or *f*, 224*r* or *f* and **266*r*** or *f*, **267*r*** or *f*, displaced 6⅔° on either side of the pairs **223, 224** or **266, 267** and all other pairs in the spark gap array, the letters *r* and *f* denoting "retard" and "faster." The latter displaced pairs of used in the control of speed of the engine rotor. The displaced pairs not shown are involved with the operation of cluth **304**, the speed changing control element.

Clutch **304** is associated with shaft **111** in that the movable element **310** draws clutch disc element **316** on shaft **111** away from clutch disc element **322** when energized by a voltage of appropriate polarity applied to its motor electromagnet **311.** Such clutch drives are well known in the art.

The clutch mechanism **304** of FIGS. **11** and **19**, when not energized is in the configuration shown in FIG. **11.** The energized configuration of clutch **304** is not specifically illustrated. Upon energization, spark-gap element **222** on disc **236** is displaced rightward, as viewed in FIG. **11**, by broken lines **236X**, into alignment with the positions of fixed spark-gap terminals **223*f***, 224*f* and **267*r***, **266*r***. When the disc is in position **236X**, the flattened edge **332** of pin **330** in disc **325** rides on surface **350** of disc **322.** Normally, the flattened edges **351** of pins **330** are engaged against the flat edge **352** in recess **331** of disc **322.** The displacement of disc **322** on shaft **111** is effected by the action of clutch **304** against spring **314** (FIG. **11**). An electric switch (not shown) of clutch mechanism **304** energizes it from a d-c power source, and has two positions, one for deceleration and one for acceleration. In either position, clutch **304** is engaged to pull clutch disc **322** from clutch disc **325**, momentarily. For the decelerate or the accelerate position, the displaced alignment of spark gap elements **222** is with the **224*f***, 223*f* and the **224*r***, 223*r* spark-gap terminal elements. However, only the **224*f***, 223*f* spark-gap elements are switched into operation with appropriate capacitors for the accelerate position, while in the decelerate position only the **223*r*** and **224*r*** spark-gap elements are switched into the circuit with their associated capacitors.

Of course, when insulative disc **236** is displaced by clutch **304**, its gap terminals **222, 225** and **228** (FIGS.

14 and 18) are all displaced into the alignment position of **236X** so as to engage the *r* and *f* lines of fixed spark gap elements. Although the accelerate and decelerate positions of disc **236** are the same, it is the switching into operation of the **223, 224** or **266, 267** exemplary *r* or *f* pairs of terminals which determine whether speed up or slow down action of the rotor will occur.

The momentary displacement of clutch disc **322** from clutch disc **325** results in rotation of disc **325** about disc **322** through an angle of 120°. The detent ball and spring mechanism **320, 321** in disc **325** positions itself between one detent dimple **328** and a succeeding one **328** at a position 120° away on disc **325.** As stated, flat **332** of pin **330** rides on surface **350** of disc **322,** and pin **330** leaves the pin-holding groove **331**/352 along ramp **333** in disc **322** during the momentary lifting of disc **322** by clutch **304.** Pin **330** falls back into the next groove **331** at a point 120° further on about disc **322.** Pin **330** falls into place in groove **331** on ramp **334.** Pins **330** are rotatable in their sockets **353,** so that for either clockwise or counterclockwise rotation, the flat **351** will engage the flat **352** by the particular ramp it encounters.

The deceleration or acceleration due to the action of clutch **304** thus occurs within a 120° interval of rotation of disc **325.** Disc **322** during this interval may only move a fraction of this arc.

There has been described hereinabove an electromotive engine system wherein at least one electromagnet is in a fixed position and a second electromagnet of similar configuration is juxtaposed with it in a magnetic polarity relationship such that, when the cores of the electromagnets are energized, the juxtaposed core faces repel one another. One core being fixed and the second core being free to move, any attachments to the second electromagnet core will move with it. Hence, if a plurality of fixed cores are positioned about a circular confining housing, and, within the housing, cores on a shaft are free to move, the shaft is rotationally urged each time the juxtaposed fixed and rotatable cores are in alignment and energized. Both the fixed and the movable cores are connected to spark gap terminal elements, and the associated other terminal elements of the spark gaps are connected to capacitors which are changed to a high voltage from pulsed unipolar signal generators. These capacitors are discharged through the electromagnets across the spark gaps. By switching selected groups of capacitors into selected pairs of spark gap elements displaced from the normal uniformly positioned elements for discharge through the electromagnets, the rotor of the circular array systems is accelerated and decelerated.

By confining a fixed electromagnet array in a linear configuration with a linearly movable electromagnet to which a working tool is attached, exciting the juxtaposed pairs of electromagnets by capacitor discharge results in the generation of linear force for such tools as punch presses or for discharging projectiles with considerable energy.

The inventor claims:

1. An electric engine comprings:

a housing;

an array of electromagnets uniformly spaced in said housing to form a stator;

a rotor cage on a shaft journaled in and rotatable within said housing and within said stator, said rotor cage having thereon a spaced array of electromagnets similar to said stator electromagnets and in number comprising an integral fraction of the number of electromagnets in said stator array;

each of the electromagnets of said stator and of said rotor having a magnetizable core of particular configuration and each being wound with a coil such that a pulse of unidirectional electric current through said coil magnetizes the respective core thereof to a particular magnetic polarity, and the faces of rotor cores juxtaposing selected stator cores are magnetized to the same polarity, the juxtaposed cores thereby tending to repel one another, one lead of each of the stator and rotor coils being connected to a common terminal, the other lead of each of said coils being connected to a gap terminal, the gap terminals of said rotor coils being on the rotor and equal in number to the number of coils thereon and matching the positions of said rotor electromagnets thereon, the gap terminals of said stator being equal in number to the number of coils on the stator and disposed uniformly about said stator to match the positions of said stator electromagnets within said housing;

a first array of capacitors each having a terminal in common with the common coil terminal of said stator electromagnets, and each capacitor having its other terminal connected to a gap terminal arrayed adjacent the gap terminal of an electromagnet associated therewith;

a second array of capacitors, each having a terminal in common with said common terminal of said rotor electromagnet coils but equal in number to the number of capacitors in said stator array, the other terminals of said capacitors in said second array being connected to gap terminals arrayed about said housing so as to be in axial alignment with said stator gap terminal positions and being alignable with said rotor gap terminals as said rotor is rotated in said housing and respective gap terminals of said rotor coils pass each second array capacitor gap terminals at a predetermined gap distance;

gap coupling terminals on said rotor equal in number to the number of rotor electromagnet coils and positioned to match the rotor electromagnet positions on said rotor, the gap coupling terminals being rotatable with said rotor so as to pass said adjacent stator coil and associated stator capacitor gap terminal at a predetermined distance therefrom;

a plurality of capacitor charging circuits connected respectively across each of said capacitors in both said first and said second arrays of capacitors for charging each of said capacitors to a predetermined high d-c potential;

a first source of unidirectional electric potential connected to each of said capacitor charging circuits for energizing said charging circuits; and

a second unidirectional electric potential source connected to said electromagnets of said rotor and said stator of such polarity as to receive a charge from the inverse inductive discharge of the electromagnet coils as their fields collapse following the discharge of each capacitor through a rotor or stator electromagnet coil,

whereby whenever a rotor electromagnet is aligned opposite a stator electromagnet, the rotor coil gap terminal of that electromagnet is opposite an associated second capacitor array gap terminal, and a gap coupling terminal of said rotor is aligned opposite the stator electromagnet coil gap terminal and associated first capacitor gap terminal, the capacitors discharge the charge thereon across the gaps through their associated electromagnet coils to magnetize their respective juxtaposed electromagnet cores to cause them to repel one another, thus aligning a succeeding pair of rotor and stator electromagnets for capacitor discharge across their respective gaps, to cause them to repel one another, alignments rotor rotation within the housing continuously bringing successive rotor-stator electromagnets into alignment for discharge of the capacitors therethrough to produce rotary motion of the rotor on said rotor shaft continuously so long as energy from said first source of unidirectional electric potential is applied to said charging circuits to recharge said capacitors after each discharge.

2. In an electric engine having a rotor comprising electromagnetic coil means rotatable within a stator comprising similar electromagnetic coil means, said electromagnetic coil means being polarized for magnetic repulsion;

capacitor means electrically coupled across successive spark gaps to selected ones of said coils of said stator and all of the coils of said rotor;

charging means connected to said capacitor means for charging said capacitor means to an electrical charge potential sufficient to cause arcing across said spark gaps to result in the discharge of said capacitor means through the electromagnetic coils so that the electromagnetic coil means repel one another; and

a unidirectional electric power source connected to said charging means to energize said charging means to continue charging said capacitor means following each discharge whereby the rotor of said engine is maintained in rotation by the successive discharges of said capacitor means across successive spark gaps into said electromagnetic coil means.

3. An electric engine according to claim **2,** wherein:

the charging means includes electronic square core oscillators connected to said unidirectional electric power source and includes step-up means and a rectifier to produce a substantial voltage step up from the voltage of said power source.

4. An electric engine according to claim **2,** wherein:

the charging means includes a vibrator connected to said power source, and step up transformer and rectifier means to provide a high voltage for charging said capacitor means.

5. A motive force producing means comprising:

at least a first electromagnet means including at least one coil wound about a core,

at least a second electromagnet means including at least one coil wound about a core similar to said first core,

the respective cores being positioned adjacent to one another so that the magnetic polarities of the adjacent core surfaces are the same when a unidirectional electric current is passed through the coils,

at least one capacitor means having one terminal thereof connected to one terminal of both of said electromagnet coils,

the other terminal of said capacitor means being connected to one terminal of a spark gap means, the other terminals of the coils of both said first and said second electromagnet means being connected to the other terminal of said spark gap means,

at least one unidirectional pulse charging means connected to said capacitor means to charge said capacitor means to a relatively high potential sufficient to arc across said spark gap means at predetermined spacing of said gap terminals, and

a source of unidirectional potential connected to said charging circuit to energize said charging means,

whereby upon application of current from said potential source to said charging means the successive pulses generated thereby charge said capacitor means to a voltage level sufficient to arc across said spark gap means to produce a discharge path for said capacitor means through said coils to cause said electromagnet means to repel one another with a substantial force.

6. A motive force producing means according to claim **5,** wherein:

said first electromagnet means is secured in a relatively stable housing, and said second electromagnet means is connected with and freely movable relative to said stable housing, and has utilization means connected thereto for performing work therewith when said capacitor means discharges through said coils of said electromagnet means.

7. A motive force producing means according to claim **6,** wherein said utilization means is a motor rotor coupled with said second electromagnet means and said first electromagnet means is a stator.

8. A motive force producing means according to claim **6,** wherein said utilization means is a piston attached to said second electromagnet means and is movable therewith to produce hammer-like blows when said capacitor means discharges through said electromagnet means.

9. In an electromotive force generating system as disclosed, means for accelerating or decelerating the motion of a force generating system, said means comprising:

at least two juxtaposed electromagnetic core elements, one fixed and one movable, including coils wound thereabout to provide a repulsion tendency when said cores are energized,

spark gap termimals connected with said coils,

capacitor means connected with said spark gap terminals to discharge across said spark gap terminals through said coils when a charge of sufficient voltage level appears across said capacitor means, thus to energize said juxtaposed electromagnets to induce said juxtaposed electromagnet cores to repel one another,

charging means connected to said capacitors for charging them to said sufficient voltage level, and

selective positioning means coupled with said spark gap terminals and with at least said movable electromagnet core to cause selective displacement of said movable core with respect to said fixed core to accelerate or decelerate the motion of the movable core relative to the fixed core.

10. An electromotive force generating system according to claim **9,** wherein:

said juxtaposed electromagnetic cores include a plurality of fixed cores and a smaller number of movable cores, said smaller number being an integral fraction of the number of fixed cores, and

said selective positioning means is an electromagnetic clutch coupled with said smaller number of movable cores for movement therewith, and includes selective displacement means coupled with said spark gap terminals connected with selected capacitors in said capacitor means and selected combinations of coils in said plurality of fixed electromagnets.

11. The method of generating motive power comprising the steps of:

a. positioning similar electromagnets in juxtaposed relationship with their respective cores arranged for repulsion when said electromagnets are energized,

b. charging capacitors to a relatively high potential, and

c. discharging said capacitors simultaneously through said electromagnets across spark gaps set to break down at said relatively high potential,

thereby to cause said similar electromagnets to repel one another with considerable force.

12. The method of generating motive power defined in claim **11,** wherein in said positioning step at least one of said electromagnets is maintained in a fixed position and another electromagnet is free to move relative to said fixed electromagnet.

13. The method of generating motive power according to claim **11,** wherein:

the charging step includes the charging of capacitors to a relatively high potential from a pulsed unipolar source of electric energy.

14. In an electromagnetic capacitor discharge engine including movable electromagnets and fixed electromagnets, said movable electromagnets being movable into polar alignment with said fixed electromagnets, capacitor means, means for charging said capacitor means, and means for discharging said charged capacitor means through said fixed and movable electromagnets to polarize aligned fixed and polarized electromagnets for magnetic repulsion, an acceleration and deceleration control means comprising:

first selective means for momentarily delaying the discharge of the capacitors until the movable electromagnets in said engine have begun to recede from the fixed electromagnets, in order to accelerate the motion of said movable electromagnets by the added impetus of the repulsion, and

second selective means for momentarily accelerating the discharge of the capacitors to occur at a point in the motion of the movable electromagnets where said movable electromagnets are approaching said fixed electromagnets to decelerate the motion of said movable electromagnet by the tendency to repel the approaching electromagnet by the fixed electromagnet.

15. An electric engine, comprising:

fixed electromagnets;

movable electromagnets movable into alignment with said fixed electromagnets;

capacitor means;

means for charging said capacitor means; and

means for discharging said charged capacitor means through said fixed and movable electromagnets to polarize said aligned fixed and movable electromagnets for magnetic repulsion.

16. An electric engine as recited in claim **15,** wherein: said means for discharging said charged capacitor means comprises voltage breakdown switch means.

17. An electric engine as recited in claim **16,** wherein:

said voltage breakdown switch means includes at least one terminal movable with at least one of said movable electromagnets for breaking down when said at least one of said movable electromagnets is in alignment with a said fixed electromagnet.

18. An electric engine as recited in claim **17,** wherein:

said voltage breakdown switch means comprises a spark gap means.

[57] **ABSTRACT**

A frequency to voltage converter including a switching circuit responsive to an input signal at each zero crossing in the positive direction to charge a capacitor to a peak negative voltage and discharging through a resistor towards a positive voltage until the next zero crossing in the positive direction. The peak voltage charge is coupled to a holding circuit to provide a D.C. voltage proportional to the frequency of the input signal.

FREQUENCY TO VOLTAGE CONVERTER

STATEMENT OF GOVERNMENT INTEREST

The invention described herein may be manufactured and used by or for the Government of the United States of America for governmental purposes without the payment of any royalties thereon or therefor.

BACKGROUND OF THE INVENTION

The invention relates to frequency to voltage conversion systems and more particularly to the concept of providing an exponential charging curve beginning at each crossover in the positive direction of a sinusoidal input signal.

Various methods for achieving an indication of the frequency of an alternating current signal have previously been devised. Such prior art circuits are not suitable where precise performance over a large dynamic range and time lag is important.

SUMMARY OF THE INVENTION

In the preferred form of the invention, an input signal (approximately sinusoidal) is shaped and differentiated by a very short time constant R.C. network. A switching circuit responsive to the negative pulse corresponding to the positive-going zero-crossing of the input signal, charges a capacitor to a peak negative voltage and is then discharged through a resistor toward a positive voltage. The peaks of the discharge waveform are sampled and then held constant until the next peak.

Other objects and many of the attendant advantages of this invention will be readily appreciated as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic circuit diagram of one embodiment of the invention;

FIG. 2 is a representation of voltages in various parts of the circuit of FIG. 1; and

FIG. 3 is a graph showing the effect of variance from the computed values for best linearity.

DESCRIPTION OF THE PREFERRED EMBODIMENT

It is well known that a linear ramp function generated at a zero crossover of an input sine wave, and allowed to rise until the next crossover, has a peak amplitude that is a measure of the length of time between crossovers. Instead of a linear ramp, the present invention utilizes an exponential curve, generated at successive crossovers of the input signal.

To obtain a voltage proportional to the frequency, f, which is the inverse of the period, T, the expression

$$e_1 = K\,(1/T_O - 1/T)$$

represents a voltage proportional to the variation of $f = 1/T$ about the center frequency $fo = 1/T_O$. K is the slope constant relating voltage and frequency, e.g. V/MHz.

A capacitor discharging through a resistance, R, from an initial voltage, $-E_1$, toward a supply voltage, $+E_2$, has an exponential discharge voltage represented by

$$e = E - (E_1 + E_2)\; exp\,(^{-at})$$

where $a = 1/Rc$.

Then at $t = T$,

$$ep = E_2 - (E_1 + E_2)\; exp\,(^{-aT})$$

where e_p is the capacitor voltage reached after discharging for a time period T.

Considered as functions of a variable T, e is a hyperbolic curve, and e_p is an exponential curve. By optimum choice of parameters, the two curves can be made to very nearly coincide over a considerable range near $T = T_O$.

The peak voltage e_p then is an instantaneous measure of the inverse period $1/T$, i.e., the frequency of the input signal.

It is obvious that $e_1 = O$ at $T = T_O$. In order that $e_p = 0$ at $T = T_O$,

$$E_2 - (E_1 + E_2)\; exp\,(^{-aT_O}) = 0$$

$$E_2 = (E_1 + E_2)\; exp\,(^{-aT_O})$$

For best coincidence of the two curves the first and second derivatives with respect to T are equated at $T = T_0$

$$e_1' = K/T^2$$

$$e_1'' = -2K/T^3 = (-2/T)\, e_1'$$

$$e_p' = a\,(E_1 + E_2)\; exp\,(-aT)$$

$$e_p'' = {}^{-ae}p'$$

From $e_1' = e_p =$,

$$K = aT_O^2(E_1 + e_2)\; exp\,(-aT_O) \text{ and}$$

from the second derivative,

$$a = 2/T_O$$

In an example for a discriminator with 25 KHz center frequency

$$To = 40\mu s$$

$$a = 2/40 = 0.050$$

$$RC = 20\mu s$$

$$exp\,(-aT_O) = 0.13534$$

$$\text{Assume } (E_1 + E_2) = 75V$$

$$E_2 = 0.1353 \times 75 = 10.1V$$

$$E_1 = 64.9V$$

The table below and the plotted voltage vs. frequency graph (FIG. 3) illustrate the effect of variance from the computed values for best linearity.

TABLE I

a	exp(−aT$_O$)	E$_1$	E$_2$	K	Frequency range linearity within 2%
0.05	0.13534	65V	10V	812	±20%
0.04	0.20190	60V	15V	969	±10%
0.029	0.31187	51.5V	23.5V	1090	± 6%

The circuit of this invention is illustrated in FIG. 1 with the waveform at various points shown in FIG. 2.

Input signal, A, is applied to high gain limiting amplifier **10** which produces a square wave output, B. Square wave B, is differentiated by short time constant RC network **12** to produce waveform C. Limiter **10** and differentiator **12** should produce pulses (waveform C) of sufficient amplitude to trigger transistor **14**, having a width not greater than one percent of T_0 and constant in amplitude and width over the expected amplitude range of input waveform, A. Transistor **14** is a PNP type which conducts only on negative pulses from differentiator **12**. The negative pulses of waveform C correspond to the positive going zero crossings of the input signal. Transistor **16** is a NPN type having high breakdown voltage and current capability, conducts heavily when transistor **14** is conducting. Capacitor **18** is charged rapidly to voltage $-E_1$, and then released and allowed to discharge through resistor **20** towards $+E_2$ as shown by waveform D. The discharge of capacitor **18** is arrested by the next charging pulse, and the sequence repeats. Resistor **20** is provided with a trim adjustment so that the operation of the circuit can be adjusted precisely to zero at center frequency.

The peaks of waveform D are coupled by emitter follower **22** and silicon diode **24** to holding capacitor **26**. The sawtooth voltage dropoff between peaks (waveform E) is caused by discharging of capacitor **26** through resistor **28**. The dropoff rate should be selected to allow the output to follow the maximum expected rate of change of frequency. RC filter **30** coupled between holding capacitor **26** and output terminal **32** removes most of the carrier frequency sawtooth from the output (waveform F).

Obviously many modifications and variations of the present invention are possible in the light of the above teachings. It is therefore to be understood that within the scope of the appended claims the invention may be practiced otherwise than as specifically described.

What is claimed is:

1. A frequency to voltage converter for producing a direct current voltage having a magnitude proportional to the frequency of an alternating input signal comprising:
   a. an input terminal for receiving an input signal the frequency of which is to be measured;
   b. a capacitor;
   c. first means coupled to said capacitor for charging said capacitor to a known voltage;
   d. discharge circuit means coupled to said capacitor and to said input terminal for discharging said capacitor to a voltage that is an instantaneous measure of the frequency of the input signal; and
   e. sampling and holding circuit means coupled to said capacitor for maintaining an output voltage proportional to the frequency of said input signal.

2. The frequency to voltage converter of claim **1** wherein said first means includes a circuit responsive to said input signal passing through zero in the positive direction to stop the discharge of said capacitor and start the charging of said capacitor.

3. The frequency to voltage converter of claim **1** wherein said capacitor charging includes a negative voltage source so that said capacitor is charged to a known negative voltage.

4. The frequency to voltage converter of claim **1** wherein said discharge circuit means includes a positive voltage source so that the capacitor is discharged towards said positive voltage source.

5. The frequency to voltage converter of claim **4** wherein said sampling and holding circuit samples and holds the positive peak voltage to which said capacitor is discharged.

6. The frequency to voltage converter of claim **1** said first means includes:
   a. a negative voltage source;
   b. switch circuit means responsive to said input signal passing through zero in the positive direction for charging said capacitor to the magnitude of said negative voltage source.

7. The converter of claim **6** wherein said switch circuit means includes:
   a. a differentiator for generating negative pulses when said input signal passes through zero in a positive direction;
   b. a first transistor coupled to said differentiator and being responsive to said negative pulse for generating a trigger pulse;
   c. a second transistor having a high breakdown voltage and a high current capability in circuit with said first transistor, said negative voltage source and said capacitor for connecting said capacitor to said negative voltage source in response to said trigger pulse.

8. The converter of claim **4** wherein said discharge circuit means includes:
   a. a positive voltage source;
   b. an adjustable resistor connecting said capacitor to said positive voltage source so that said capacitor will discharge toward said positive voltage source.

METHOD AND APPARATUS FOR PRODUCING NUCLEAR-FUSION REACTIONS

Philo T. Farnsworth, Fort Wayne, Ind., assignor to International Telephone and Telegraph Corporation, a corporation of Delaware

Filed May 13, 1966, Ser. No. 549,849
19 Claims. (Cl. 176—1)

ABSTRACT OF THE DISCLOSURE

A method and apparatus for producing controlled nuclear-fusion reaction by use of self-generated electric fields and inertial ionized-gas containment. The apparatus comprises a spherical anode which concentrically surrounds a cathode. A plurality of ion guns are mounted on the exterior of the anode in spherically spaced and diametrically aligned relationship such that the beam axes intersect at the center of the cathode. Appropriate apertures are provided in the cathode for passage of the ions. Other apertures permit passage of positively charged particles outwardly from the cathode interior, but are biased negatively to prevent the flow of electrons into the interelectrode space.

A voltage is applied between the anode and cathode. Ions from the guns are propelled and focused into the center of the cathode establishing in the cathode interior a series of concentric spherical sheaths of alternating maxima and minima potentials called "virtual electrodes." The ions in the innermost "virtual electrode" have fusion energies, and are contained at a density sufficient to produce a self-sustained fusion reaction.

I. *Introduction*

The present invention relates to a method and apparatus for producing nuclear-fusion reactions, and more particularly to a method and apparatus for producing controlled nuclear-fusion reactions by use of self-generated electric fields and inertial ionized gas containment.

In the well-known fusion reactions, nuclei of two light elements are combined to form a nucleus of a single heavier element, together with a release of the excess binding energy in the form of sub-atomic particles (neutrons and protons). Before the positively charged nuclei can be brought close enough together for fusion to take place, sufficient energy must be supplied to overcome the forces of electrostatic repulsion between them. There are many possible reactions involving the combination of two light nuclei which are accompanied by the release of energy, but hydrogen isotopes (deuterium and tritium) and helium, under the proper circumstances, are considered to be the most likely to produce controllable fusion reactions. Examples of these reactions are:

(1) ${}_1D^2+{}_1D^2\rightarrow{}_2He^3$ (.82 mev.)$+{}_0n^1$ (2.45 mev.)
(2) ${}_1D^2+{}_1D^2\rightarrow{}_1T^3$ (1.01 mev.)$+{}_1p^1$ (3.02 mev.)
(3) ${}_1D^2+{}_1T^3\rightarrow{}_2He^4$ (3.5 mev.)$+{}_0n^1$ (14.1 mev.)
(4) ${}_1D^2+{}_2He^3\rightarrow{}_2He^4$ (3.6 mev.)$+{}_1p^1$ (14.7 mev.)

It has been determined that to produce a "self-sustained fusion reaction" (release of more energy from the reaction than is required to produce it) the density of the fusionable particles must be maintained at a high order. It is generally accepted that if such a density could be so contained, the other problems involved in producing a self-sustained fusion reaction, principally that of raising the particle energy-levels high enough to overcome their repelling forces, could be solved. Most suggestions and proposals for plasma containment employ very high magnetic fields; these include the pinched discharge, the

Stellerator, the magnetic mirror, the Astron, and the like. This invention departs widely from those approaches by utilizing self-generated electric fields for containing the ionized gases. Through the use of such electric fields, many, if not most, of the complex problems inherent in the magnetic-field devices have been overcome.

Methods and apparatus capable of producing such continuous reactions are disclosed and claimed in my application Ser. No. 165,639, filed Jan. 11, 1962, entitled, "Electric Discharge Device for Producing Interactions Between Nuclei," now U.S. Patent No. 3,258,402, issued on June 28, 1966. Generally speaking, one form of the invention of my aforesaid application is of spherical geometry, in which an electron-emissive cathode concentrically surrounds a shell-like anode having an inner concentric cavity or space. The anode is permeable to the flow of atomic particles, while the cathode is not. In operation, an electrical discharge, composed of high-order magnitude electron and ion currents in the space enveloped by the anode, produces a radial potential distribution which is, generally speaking, a minimum adjacent to the center of the anode cavity and a maximum adjacent to the anode wall. Ions created at points intermediate the center and the anode wall fall toward and oscillate through the center at velocities which are dependent upon the operating potentials, the potentials developed within the anodic space and the potentials at which the ions are born. With developed potentials of sufficiently high magnitude, the ions are propelled at nuclear reacting energies, so that ion collisions occur at the center and thus produce nuclear-fusion reactions.

The present invention structurally differs fundamentally therefrom in the respect that the cathode and anode elements are reversed, and the anode therefore surrounds the cathode. The cathode is substantially impervious to the flow of electrons therethrough and is reasonably permeable to the free flow of positively charged particles, while the anode shell is not. An electrical gaseous discharge developed within the device causes the concentration of electrons and ions toward and into the central structureless zone of the volume enclosed by the cathode, thereby producing in said zone concentric, abrupt, shell-like, potential barriers of alternating polarities or virtual cathodes and anodes. High-energy ions within the space of the structure are propelled toward and through these virtual electrodes to the geometric center of the structure, there producing, in concert with the low-energy ions created in that region, an ion concentration of extremely high density. When the space charge in the center fully develops, the potential difference between the innermost virtual cathode and the first adjacent virtual anode reaches a magnitude sufficient to propel ions through the center at fusion-reacting energies. Atomic and sub-atomic products produced by these reactions are available for the production of useful power. The present invention involves novel and improved means and methods for confining the ionized gas particles, regardless of the charge; compressing them into small volumes with high densities; and then maintaining them in a stable condition for a prolonged and continuous period of time.

It is, therefore, an object of the present invention to provide a method and means for compressing and confining an ionized gas discharge by the use of self-generated electric fields.

It is another object of the present invention to provide an electric-field method and means for producing a stable electric discharge.

It is still another object of this invention to provide a method and apparatus for converting the energy released from the nuclear reactions into useful heat energy.

It is another object of this invention to provide a method and apparatus for converting positively-charged particles from the nuclear-fusion reaction directly into electrical power.

It is still another object of this invention to provide a source of electrical power and heat in which the kinetic energy of the products of the nuclear-fusion reactions are converted directly into electrical power with or without accompanying neutrons.

II. *Description of theoretical device*

In the accomplishment of the above and related objects, an electric discharge device has an anode which surrounds a cathode that electrically encloses a structureless space or volume. The cathode is rendered practically impervious to electrons but reasonably pervious to ions. The anode and cathode are uniquely designed and assembled to form an electron-optical system wherein the cathodic space is maintained completely filled with the electrical discharge. Traversing electrons, under the influence of the electron optice, follow radial-like paths through the cathodic space and, as the cathode is quite impervious to electrons, they are thereby kept from being intercepted in appreciable numbers by the surrounding anode. Electron energy spread is thus maintained at minimum values, and there is developed a high-magnitude electron circulatory current which serves to produce the required potential gradient in the cathodic space.

A variety of fusion reactions are possible, with certain of the reactions being useful in directly generating electrical power. The charged particles of these particular fusion reactions are emitted at sufficient kinetic energies to overcome the decelerating field of the anode. This results in the particles, charged positively, performing work against the anode field, and thereby augmenting the energy stored in that field. The remainder of the energy is converted into heat at the anode, but the deposit of the positive charges thereon results in their conversion directly into electrical energy or power. Energy converted into heat also may be utilized in the generation of power.

The above-mentioned and other features and objects of this invention, and the manner of attaining them, will become more apparent and the invention itself will be best understood by reference to the following description of embodiments of this invention taken in conjunction with the accompanying drawings, wherein:

FIG. 1 is a diagrammatic illustration of an embodiment of the present invention used in explaining the theory of operation;

FIGS. 2 and 3 are potential distribution curves used in explaining the operating principles of this invention;

FIG. 4 is a simplified diagram used in explaining the theory of charged particle scattering;

FIGS. *5a, 5b,* 6, *6a, 6b, 6c,* 7 and 8 are graphs used in explaining the principles of this invention;

FIG. 9 is a further diagrammatic illustration of an embodiment of this invention (more elaborate than FIG. 1) used in explaining the theory of operation;

FIG. 10 is a graph of the deuterium-tritium reaction used in explaining the operation of this invention;

FIG. 11 is a partial diametral cross-section of a working embodiment of this invention;

FIG. 12 is an axial section of one part of the terminal and supporting structure for the embodiment of FIG. 11;

FIG. 13 is a fragmentary axial section of one ion gun of FIG. 11;

FIG. 14 is an enlarged fragmentary plan view of a cathode biasing screen assembly of FIG. 11;

FIG. 15 is a cross-section taken along section line **15—15** of FIG. 14;

FIG. 16 is an enlarged fragmentary plan view of an ion aperture assembly of FIG. 11;

FIG. 17 is a cross-section taken along section line **17—17** of FIG. 16;

FIGS. 18*a* and 18*b* are diagrams used in explaining the relative positions of the ion guns and the screen-covered apertures in the cathode;

FIG. 19 is an end view of an ion gun;

FIGS. 20 and 21 are cross-sections taken along section lines 20—20 and 21—21, respectively, of FIG. 13;

FIG. 22 is a cross-section taken along section line **22—22** of FIG. 11;

FIG. 23 is a partial cross-section of another working embodiment of this invention;

FIG. 24 is an enlarged fragmentary cross-section of the biasing screen assembly mounted on the cathode shown in FIG. 23;

FIG. 25 is an enlarged fragmentary cross-section of the ion-aperture assembly mounted on the cathode shown in FIG. 23;

FIG. 26 is an enlarged fragmentary cross-section of the terminal assembly for applying the biasing voltage to the biasing screen assembly of FIGS. 23 and 24;

FIG. 27 is an enlarged, fragmentary sectional view of another embodiment of an ion gun assembly;

FIG. 28 is a cross-section taken substantially along section line **28—28** of FIG. 27; and

FIG. 29 is a cross-section taken substantially along section line **29—29** of FIG. 27.

III. *Simplified explanation of operation*

It has been accepted that fusion reactions, which will yield more energy than that supplied to produce the effect, will occur only in high-density plasmas in which the overall kinetic energies of the ions composing the gas are high enough to overcome their mutual repelling forces. Most approaches proposed or under study to produce these conditions employ powerful external magnets to contain and compress the plasma into a small volume to increase the density and temperature (energy) of the particles therein. Such magnetic fields thus far have been successful in confining the plasma particles in the required high-density configuration for only extremely short (microseconds) fusion reactions. The time required to produce the favorable conditions (interval between pulses) is so great that energy output is extremely small when compared with the energy input.

This invention differs fundamentally from those in that charge-particles are compressed into a suitably dense configuration through the action of an "electrodynamic lens" established by confined bi-polar charges in a volume of free space. Such bi-polar charges are developed into a spherical configuration in such a way as to establish a plurality of concentric spherical potential sheaths radially spaced, these sheaths having large potential differences therebetween. The maxima and minima potential sheaths alternate radially and are characterized, respectively, as virtual anodes and cathodes. A virtual cathode is innermost and substantially coincident with the geometric center.

From this arrangement to virtual anodes and cathodes, a radial potential distribution obtains in a spherical space, with one potential minimum being near the center. Thus positively charged particles in this space fall toward and through the center; hence, in effect they are focused onto the center. The focusing forces may be considered as resulting from bi-polar (electron-ion) charge optics.

Bi-polar charges moving radially within the space produce a radial potential distribution as described above. It is, therefore, convenient to characterize these bi-polar charge optics as "Poisson Optics" inasmuch as the solution of Poisson's differential equation (given later on) for the radial potential distribution resulting from bi-polar charges in a spherical configuration reveals the phenomenon of the aforedescribed virtual anodes and cathodes. The electric field which obtains within this free space occupied by these virtual electrodes I call a "poissor."

The trajectories of the charged particles are determined by the composite field or poissor which is produced by the aggregate of the fields of the oppositely charged particles. When a positively charged particle (ion) of zero velocity falls from a point just inside a virtual anode (which defines a spherical positive-potential boundary), it is accelerated toward the adjacent virtual cathode and, in passing beyond it, decelerates toward a condition of zero velocity at an equipotential boundary of that from which it started, and then repeats this velocity rate of change from zero to maximum, and then again to zero in the opposite direction. Electrons likewise will oscillate through virtual anodes between negative equipotential barriers. Since one polarity of charged particle approaches its maximum velocity while the other polarity approaches its minimum, the two species maintain their separate identities and spaced charges. Hence, it is seen that the particles are trapped inertially between such equipotential boundaries; accordingly, I call my method for containing the nuclear-fusion reacting particles "inertial containment." The ions which are created on the inward sides of the boundaries of the spherical virtual anodes and which oscillate through or near the center of the device produce the required density thereat to satisfy the conditions for a self-sustaining nuclear fusion reaction. Thus, the charged particles are literally compressed into the required density in the central region by the process of inertial containment, and the present device utilizes this process.

Referring to the drawings, and more particularly to FIG. 1, an evacuated spherical electron-tube structure is shown which comprises a spherical, anode shell **20** at radius r_a, enclosing a sperical, cathode shell **21** of radius r_c, and an ion gun **22** which is mounted on the outside of the anode **20** as shown. The anode and cathode electrodes are concentrically arranged as shown. The cathode **21** and its field are substantially impervious to electron flow to the anode **20**, but is pervious to the flow of positively charged particles such as ions. In this theoretical exemplification, the cathode **21** may be considered as an open-mesh electrode formed of metallic screen or the like, which is constructed of a material, the surface of which emits electrons upon bombardment by ions or electrons and preferably is photoelectric in the ultra-violet spectral region. Suitable connections are made to the electrodes, a lead **23** being connected to the anode **20** for applying a positive potential thereto and another lead **24** being connected from the cathode **21** for connection to a negative potential terminal. A power source, such as a battery **25**, delivering a suitably high voltage is connected as shown to the leads **23** and **24**. In the preferred embodiment of this invention, the anode **20** is operated at ground potential.

In one embodiment of this invention, ions of a suitable nuclear-fusion reactive gas are introduced into the space enclosed by the cathode **21**. An electrical discharge composed of high-magnitude electron and ion currents forms in the cathodic volume and develops a difference of potential which is, generally speaking, a minimum near the geometric center **26** and a maximum adjacent to the anode **20**, with one or more potential maxima (virtual anodes) and minima (virtual cathodes) concentrically enclosed within the cathode **21**. Ions created at points adjacent to potential maxima (virtual anodes) fall toward and oscillate through adjacent potential minima (virtual cathodes) with energies equivalent to the potentials at the points where they start their journeys. These ions, falling inwardly toward the center **26** from regions of high potentials, will be propelled at velocities (energies) which are sufficient to overcome the repelling forces of other high-energy ions and also the slower (target) ions born in the region near the center **26** and collide, thus producing nuclear-fusion reactions.

In order to obtain ions with fusion-reacting energies, the sizes of the virtual cathodes and anodes must be maintained such that the boundaries thereof are well defined, and the potential differences therebetween are pronounced. This is achieved by methods which are explained in detail in the written description later following.

IV. *Description of poissor (virtual-electrode system) formation*

With suitable potentials applied to the electrodes, and with the ion gun **22** energized, ions of a fusion reactive gas are directed into the space enclosed by cathode **21**, where they will be accelerated radially inwardly toward the geometric center **26**. Since there is a potential gradient between the anode **20** and cathode **21**, the positively charged ions, as indicated by the numeral **27**, will be accelerated by the cathode **21**. Inasmuch as the latter is substantially ion permeable, each ion **27** will continue its transit and, if the optics are considered to be perfect, it will pass through the center **26** and travel onwardly in a straight line until the repelling field of the anode **20** at about the point **28** is reached. At this point, the direction of travel of the ion will be reversed, and it will repeat the diametric excursion to the opposite side of the device adjacent to the anode **20**, passing through the center **26** enroute.

Because the potential within the cathode is uniform (assuming no other ions or electrons are in existence), ions **27** will experience no velocity-changing force while traveling therethrough. Thus, an ion may be considered as starting its travel at or near a given point on the anode, accelerating toward the cathode, traveling with constant velocity through the cathodic space, and then decelerating from the cathode to the vicinity of the anode where its velocity becomes zero and it reverses its direction of travel. This ion will continue its oscillatory motion until it is lost by one of several competing actions, which will be explained later on. The significance of this single-ion concept is two-fold: firstly, it recognizes that the normal space potential inside cathode **21** is uniform at the value of the cathode, and an ion traveling thereacross does so with uniform velocity; and secondly, that the ion will oscillate within the space enclosed by anode **20** until ultimately collected by the cathode **21**.

Now let it be assumed that two ions leave the anode simultaneously from diametrically oposite points, such as from ion guns **22** and **22***a*. Each of these ions will be propelled radially inwardly toward the exact center **26** of the cathodic space so that they would collide at that point in the absence of any other forces. Inasmuch as each ion is positively charged, it will exert a repelling force upon the other, such that their respective velocities will be progressively decreased until they nearly reach the exact center **26**, where they will have given up all of their energies and stop. Under the repelling influence of their respective fields, they will reverse their direction of travel and be accelerated outwardly. In a practical embodiment, however, the ions will experience a diverting effect and will pass each other at minimum velocity rather than stopping. Upon passing through the cathode **21**, the ions will be decelerated by the anode **20** field until they stop adjacent to the anode **20**, whereupon the cycle is repeated. Even though the unipotential space inside the cathode **21** exerts no force on a single ion passing therethrough, two ions approaching each other along a diametral path experience coulomb repulsion and velocity changes which serve to create a positive electric field in the cathodic space, the maximum effect occurring in the central region where the velocity is the least. This may be properly described as a space-charge effect.

Now assume that a copious quantity of ions are introduced into the space immediately adjacent to the anode **20** from a number of symmetrically disposed ion guns. These ions will converge toward the center **26** at progressively decreasing velocities until they reach a minimum velocity and thereafter diverge outwardly along essentially the same diameters, accelerating until they pass out through the cathode **21**. The ions contribute a positive charge to the cathodic space which increases progressively as the coulomb forces become effective and reach a maximum within center **26**; as the ions leave the center **26**, they absorb energy from that field on their passage to the cathode **21**. Thus, surrounding the cathodic center **26** (and inside the cathode **21**), a virtual anode will be produced which can be made to have a potential which can exceed that potential (V_a) of the anode **20** by a factor ΔV_a equal to the average voltage increase which is required by the ions from the ion guns to penetrate the anode **20** field. The ions, therefore, oscillate back and forth through the permeable cathode **21** until lost by one of several competing actions which will be explained later, since they do not re-enter the anode **20**.

The establishment of the ion space-charge inside the cathode **21** may be better understood by reference to the graph of FIG. 2 wherein the abscissa represents the radius of the device and the ordinate represents the potential distribution therein. The magnitude of the ion space-charge is dependent upon the amount of space-charge current flowing in the cathodic space. For a minute quantity of current, the positive charge contribution is small, and the potential at the center would appear as shown by curve *a*. A larger current will produce a more positive potential distribution such as curve *b*. Greater or lesser currents will change the potential at the center **26** correspondingly.

Since the cathode **21** is not completely permeable to the flow of ions therethrough, ions will impact it and dislodge secondary and Auger neutralization electrons thereby. (During operation of the device, electrons also will be supplied from the photoelectric cathode **21** by ultra-violet radiation from Bremsstrahlung and recombination.) Electrons, to be able to leave the cathode **21**, must be excited to a potential ($V_c+\Delta V_c$), V_c being the potential of the cathode **21**. The electrons so emitted by cathode **21** will leave with a Fermi-Dirac distribution of velocities and the potential gradient near the cathode **21** thereby becomes more negative by the factor ΔV_c than that of cathode **21**, and the potential curve moves down until it has a minimum at a radius r_{c_1}, close to that of the cathode **21**, at which the potential corresponds to the average velocity of emission. For this condition, most of the electrons are slowed down until they come to rest, thus creating a virtual cathode **29** at a radius r_{c1}, and from which the electrons may flow in either direction, i.e., either return to the cathode **21** or flow into the central cathodic volume.

Some electrons, under the attractive influence of the positive potential gradient (virtual anode) created in the central volume by the ions and the repelling influence of the virtual cathode **29**, will be accelerated toward the center **26** until their mutually repelling coulomb forces predominate. They then will be decelerated, giving up kinetic energy to the field, and ultimately may be scattered through large angles, returning to the virtual cathode **29**, where they will repeat the cycle. Since the electron density is the greatest in the small spherical volume enveloping the center **26**, the negative space-charge contribution by the electrons will be the greatest in that region and a potential minimum or a crater will develop in the center of the positive gradient *b* (FIG. 2) which will increase in depth until a virtual cathode **30***a*, with a potential equal to that of virtual cathode **29**, is created at the center **26**, radius r_0. This action is accompanied by an outward displacement of the peak of the positive potential gradient to a radius r_{a_1}, where a spherical potential sheath or virtual anode **31** is formed.

The description thus far has disregarded the presence of neutral gas molecules within the device. When neutral gas is present, it initially will be distributed equally throughout the volume enclosed by anode **20**. The electrons and ions oscillating within the cathode **21** space will strike the neutral gas molecules, creating additional electrons and ions which, under the influence of the electric fields, will be set into oscillatory motion, the lengths of their respective paths being determined by the potentials at the points within the cathodic space where they were created. For example, suppose an ion is born in the outward (cathode) side of the virtual anode **31** (FIG. 2); it will be propelled through the virtual cathode **29** and impact the cathode **21**, thereby producing additional electrons. The electron which was released during the creation of the ion will pass through the virtual anode **31**, and be brought to rest in the vicinity of the virtual cathode **30***a* where, neglecting any deviation, it will reverse its direction and return to the point where created. Now suppose the ion and electron were created on the inside of virtual anode **31** (FIG. 2). The ion will move inwardly, being accelerated toward and through the virtual cathode **30***a*, and will come to rest at the positive barrier on the opposite side of the center **26**, and then oscillate between those barriers. The electron will be propelled through the virtual anode **31** and will go into oscillation between the virtual cathode **29** and the virtual cathode **30***a*. By far the greatest number of ions (and electrons) will be produced near the virtual cathode **30***a*, because the probability of ionization by electron impact is greater the slower the electron and because the electron density is the greatest in the virtual cathode.

As the process continues, the ion and electron space currents tend to build up a small positive potential maximum within the virtual cathode **30***a* (FIG. 2) by virtue of the ions that are created in that region and which oscillate through it. Thus, a vestigial virtual anode **32** (FIG. 3) is formed in the center **26**, and the virtual cathode **30***a* moves to a new location **30** at radius r_{c_2}. When neutral, gas molecules are present in the virtual cathode, ionization will occur. The electrons so created will be nearly indistinguishable from and react in the same manner as those in the virtual cathode, i.e., they will be accelerated outwardly toward a virtual anode. The associated ions will be born with the very low kinetic energy of the neutral particles and therefore will remain in the vicinity of the virtual cathode, neutralizing some of the space charge. These combined actions of electrons and ions will result in smaller negative space charge which decreases the radius of the virtual cathode. The new radial potential distribution is shown in FIG. 3. It will be noted that an increase in the electron space-charge current within the virtual anode **32** could result in the formation of a new virtual cathode therein. This process of adding virtual electrodes, theoretically, could continue until a point of confusion is reached where they merge and the field collapses. In actual practice, however, the number of virtual electrodes in a poissor may, and will, be controlled. In the practical exemplifications described herein, only two virtual cathodes (**29** and **30**), one virtual anode **31** and the vestigial anode **32** will be assumed to exist.

It must be borne in mind that in an actual operating device neither the ions nor the electrons are traveling precisely radially; moreover, there is a velocity spread within both the ion and electron groups due to interparticle scattering. As a result, the points where ions and electrons reverse their direction of motion do not lie on mathematically thin surfaces; accordingly, the virtual anodes and cathodes have finite radial thicknesses which are called "potential gradient sheaths" or simply "sheaths."

At this point, it will be appreciated that the space charge buildup inside the cathode **21** has resulted in the development of concentric potential gradient sheaths which serve in confining negatively and positively charged particles to movement in paths, almost all of which intersect at the center **26**, while others oscillate along path lengths which are determined by the energy levels at which the charged particles were created. When a high kinetic energy ion (projectile) passes near a low kinetic energy ion (target) in the central volume, scattering occurs. An energy transfer takes place therebetween which sets the target ion into oscillation and tends to trap the projectile. The positively charged particles for fusion reactions thus are compressed into such a densely packed volume concentric with the geometric center **26** that the probability of those particles being fused is high.

The manifestation of a poissor (virtual-electrode system) by radiation of light within spherical geometries similar to the device described above has been observed through viewing ports and studied photographically, on many occasions.

V. *Other atomic processes in the discharge*

In the immediately preceding discussion, the ions and electrons have been considered as moving past each other, interacting only through their respective space charges. There are a number of other atomic processes which can occur, however, and it will be shown in the following that the design of the apparatus can be such as to minimize some of these effects and use others to good advantage.

As has already been explained, the high-energy ions or electrons, in the absence of outside influences, would oscillate radially through the space of the anode **20** or the cathode **21** (FIG. 3). The ion transit time between the limits of its travel, i.e., the time which an ion takes for one traversal of its path, is proportional to the ion path length and inversely proportional to its average velocity. This ion oscillatory action will, in the presence of electrons and neutral gas, continue only until one of four possible actions occurs:

(a) the ion path is altered by the "scattering process";
(b) the ion "captures" an electron from a neutral atom, called charge exchange, or recombines with an electron and becomes a neutral atom;
(c) the ion is fused by a nuclear reaction; or,
(d) the ion is captured by the cathode or the anode wall.

A scattering event is a collision of or near collision of two or more particles in which the energies and momentums of the individual particles are altered, but total energy and momentum are conserved. In an ionized gas, ion-ion scattering and electron-electron deflections from coulomb forces are of primary importance because energy is most readily transferred between particles of similar masses. Electron-ion deflections involve much less energy transfer because of the large mass difference between the two species.

"Scattering" is the total statistical effect of the probability of electrostatic deflection of like particles with boh radius and distance as variables; i.e., the deflecting of particles of like charge by the coulomb repelling forces. Ion scattering takes place mostly in the virtual anodes where the kinetic energies are low and the ion densities are many fold greater than anywhere else along the ions' paths. Scattering in the virtual anodes cannot result in a large energy transfer. When an ion is scattered in a virtual anode and is accelerated toward a virtual cathode, it gains high kinetic energy and its path is essentially radial. (As the ions and electrons are oscillating within a spherical enclosure, their current densities increase radially inwardly as $1/r^2$ where r is the distance from the geometric center **26** to the point where the density is measured.) An ion will be deflected from its path as it approaches another ion if it is unable to approach closely enough (within the radius of fusion, r_f) for the sub-atomic attractive nuclear forces to predominate. This particular distance between two ion (r_f) where scattering is replaced by fusion, can be calculated if the fusion cross-section for the particular ion is known. For example, if we assume that the fusion cross-section (σ_f) for tritium ions with deuterium ions is:

$$5\times10^{-24}\text{ cm.}^2$$

then

$$\pi(r_f)^2=\sigma_f=5\times10^{-24}$$

$$r_f=\sqrt{\frac{5\times10^{-24}}{\pi}}\simeq1.26\times10^{-12}\text{ cm.} \tag{5}$$

If scattering is too great, it will not be possible to maintain the high ion density at the center **26** necessary to assure the required fusion probability. In other words, the effect of scattering is to increase the size of the minute volume of the central vestigial virtual anode **32**. Thus it becomes advantageous to limit the number of ion trips through the center, for a given particle energy, in order to prevent an increase in that volume by scattering.

The deflection angle will depend upon how closely the two ions approach each other, this angle being directly proportional to the density of the target ions bound within the innermost virtual cathode **30** (FIG. 3) and inversely proportional to the square of the energy of the scattered ion. Ions which approach each other at a distance less than r_f will fuse; those that are unable to close within that range will be deflected. The scattering angle will be greater the closer the ions come to each other. The critical angle where fusion occurs, called the "angle of fusion," can be calculated using Rutherford's formula. Neglecting multiple scattering for the tritium-deuterium ions, this angle turns out to be 58°; thus, scattering will take place only when the angles are less than 58°. It can be shown mathematically that the probability of the scattering angle exceeding 8° is only about 10%.

As an ion has a much shorter wavelength than an electron, its atomic dimensions are much smaller. Two important consequences follow:

(a) Diffraction effects will not occur in elastic scattering. Thus, over a major part of angular range, elastic scattering will be the same as that given by the classical theory. (At very small angles, the quantum theory will give better results.)

(b) Elastic scattering will be confined to very small angles. The scattered intensity will decrease with an increase of scattering angle, and the scattering is concentrated to small angles as the incident energy is increased: the total scattering will decrease with increasing energy.

For elastic collisions, the cross-section will be small if:

$$\frac{r}{v}\times de\gg\frac{h}{2\pi} \tag{6}$$

where

de=ionization energy
h=Planck's constant
v=velocity of the ions
r=radius of ion deflection

The greater the value of de, the greater will be the energy at which maximum inelastic cross-section will occur. Because of small values of de, charge-exchange is the most important inelastic collision process.

An ion can be neutralized by an encounter with an electron. This can happen in two different ways: an ion can collide with a neutral atom and rob it of its electron ("charge-exchange"), or the ion may collide with the free electron and recombine to form a neutral atom. The probability of recombination is extremely unlikely compared to charge exchange (see Brown, "Basic Data of Plasma Physics," Wiley, 1959, page 104) and will occur only if the two colliding particles are traveling in the same direction at about the same velocity. Since the charge-exchange cross-section is greater than 10^{-16} cm.^{2} between 1 kev. and 50 kev., charge exchange will occur over a wide range. The gentler the slope of the potential gradient, the longer will be the ion path length within which charge-exchange can occur. The only region in which recombination can occur is close to the virtual cathodes **29** and **30** where the electron velocity is lowest and ion velocity is highest.

When charge-exchange occurs, there is very little energy transfer between the two particles other than the transfer of an electron from one nucleus to the other. The old ion, which becomes a neutral atom, retains almost all of its velocity, and, since it is no longer influenced by the electric field, it simply travels onwardly until it is lost at the tube wall. The newly formed ion has the energy corresponding to the potential at the point in space where it was created. It begins an oscillatory motion of its own through the center 26, or travels to the cathode 21 with no indication of having been previously deflected. The newly formed ion may be considered to be continuing to increase the average number of trips started by the old ion, but with the disadvantage of having suffered an energy loss. The ion charge-exchange cycle of the inner side of the virtual anode 31 may be repeated several times before the energy loss becomes so great that fusion will not occur.

When recombination occurs, a neutral atom results, which travels outwardly until it is either reionized by another electron or ion or migrates to the tube walls. Recombination results in a loss of energy through radiation as well as a loss of both ions and electrons from the space charge; it is fortunate that the probability of this event occurring is so low and thus represents a negligible energy loss. This condition is achieved by maintaining the paths of the electrons as nearly radial as possible. One means for obtaining this radial motion is to hold the velocity spread of the electrons to a minimum.

Control of charge-exchange by limiting ion trips

Ion scattering will be limited if the number of ion trips through the center of the device can be limited. It will now be shown that this number of ion trips hence charge-exchange can be controlled.

The extent of charge-exchange may be calculated from the relationship which expresses that probability per trip P_c as follows:

$$P_c = \rho_n \times \sigma_c \times L \tag{7}$$

in which:

L=the length of one ion path in centimeters;

ρ_n=the neutral gas density in particles per cubic centimeter; and

σ_c=the charge-exchange cross-section in cm.^{2}.

The highest possible value for P_c is unity (1), since this means that the event of charge-exchange occurs. The obvious minimum value of P_c is zero (0). From the formula, if the calculated value for P_c is 10^{-6}, this means that an ion makes on an average 10^6 oscillatory trips before the energy loss of the ion by charge-exchange becomes so great that it will not be able to reach a fusion radius. Values for charge-exchange cross-section may be obtained from the curve of Jackson & Schriff in "Physical Review," vol. 89, No. 2, page 359, 1953.

In the case at hand, it is desirable to limit the number of ion trips to less than one million during the occurrence of from four (4) to six (6) charge-exchange cycles. If an average of four (4) captures per 10^6 is assumed, then:

$$P_c = \frac{4}{10^6} = 4 \times 10^{-6}$$

Now assuming as an example that the path length is 0.135 centimeter and the value of σ_c is 10^{-16} cm.^{2}, then the value of the neutral gas density ρ_n may be derived from Equation 7 as follows:

$$\rho_n = \frac{P_c}{\sigma_c \times L} = \frac{4 \times 10^{-6}}{10^{-16} \times 0.135} = \frac{1}{250{,}000 \times 10^{-16} \times 0.135}$$
$$\simeq 3 \times 10^{11} \text{ particles/cm.}^3$$

Thus, it is readily observed that the control of charge-exchange, which in turn governs to a major extent the shape of the potential distribution, is achieved by adjustment of gas density as charge-exchange cross-section is inversely proportional to gas density. Thus it is desirable to work at the lowest practicable gas density.

Maintaining radial thinness of virtual cathode by controlling electron scattering

During space charge build-up, electrons initially have energies for oscillating within the confines of the cathode 21 along radial paths which pass through the center 26. These electrons suffer the same type of deflective forces as approaching ions, such that meeting electrons scatter. Electrons approaching each other at or near the center 26 deflect along different paths which are also radial. However, if the electrons should meet at points other than the center 26, they will deflect along new paths which may become either more radial or less radial. As the electron transits continue, the non-radial electrons can and do meet with other electrons, producing further non-radial and radial electrons such that eventually, after a relatively large number of electron transits, electron movements inside the cathode 21 tend to become, in some measure, non-radial. FIG. 4 shows a simplified example of this deflection for two different locations of an electron (33 and 34) with respect to an electron traveling along a non-radial path. In FIG. 4, the electron 33 is deflected along the new (and radial) path, while electron 34 is deflected along a more non-radial path. If the deflection angle is large, some of the electrons could, unless otherwise prevented, acquire sufficient energy to penetrate the virtual cathode 29 and the cathode 21 and be absorbed by the anode 20 or to enter the cathode 21 and thus be removed from the field; others will accumulate orbital momentum.

The required condition for producing sharply resolved virtual anodes and cathodes is initially achieved by controlling the number of electron trips within the cathodic space. This condition may be represented by the equation:

$$I_e = 2\overline{N}_e \times i_{e2c} \tag{8}$$

where

I_e=the circulatory electron current through the virtual anode 31 inside the cathode 21 (FIG. 3),

i_{e2c}=the electron current emitted from the inner surface of the cathode 21 (FIG. 3),

$\overline{N}_e$=the average number of electron trips ($2\overline{N}_e$ is the average number of round trips).

If a particle's path is through the center, the distance from its starting point to the point where it commences its return journey is the equivalent of two trips or one "round trip." Where the path of the particle is away from the center, the distance from its point of origin to its reversal point is one trip. It is desired that the factor $\overline{N}_e$ fall somewhere between the figures of 10^3 and 10^4. If $\overline{N}_e$ becomes too large, the virtual cathodes and anodes will not form properly. Thus, by preventing the number of electron trips from becoming excessive, the non-radial component of the electron space-current can be held to a minimum.

The number of electron trips may be made relatively small by maintaining a high electron current density within the cathodic space. Since the maximum value of the circulatory electron current I_e is limited by space-charge saturation, which is a function of the cathode voltage gradient, I_e (Equation 8) may be made to approach its saturation limit by increasing the cathode current i_{e2c}, thereby confining a very large number of electrons within the cathode 21 which make but few round trips. Accordingly, few orbital electrons will be formed. In a practical device, the electron current can be increased by the use of electron emitters within the cathode 21.

The paths of the orbiting electrons are elliptical, and each such electron is therefore subjected to a precessional force which causes the electron's path to sweep a spherical surface inside the cathode. These electrons contribute to the electron circulatory current and also to the fields of the virtual cathodes. Because of their elliptical paths, with non-radial velocity components, orbital electrons cannot approach the virtual cathodes as closely as radial electrons. Thus, their maximum space charge contributions occur farther from the virtual cathodes than those from radials, and the virtual cathodes will tend to be displaced inwardly. Excessively large numbers of orbital electrons (greater than 10% of the electron circulatory current) therefore are undesirable as they prevent the maintaining of sharply defined virtual electrodes. In actual practice, the orbital electrons appear not to exceed that limit.

Orbital electrons, in addition to their contribution to the electron circulatory current, further reduce the probability of recombination. In the fusion-reaction volume enclosed by the virtual cathode **30**, this becomes extremely important as it greatly reduces the loss of fusion-reactive ions from that region. In the region outside of the virtual cathode **30**, the orbital electrons, as previously shown, not only contribute to the field which maintains the virtual cathode **29**, but also displaces that cathode inwardly toward the virtual anode **31** and thereby reduce greatly, any cusps or singularities in the electric field pattern of the virtual cathode **29** produced by the anode **20** field penetrating through the apertures in the cathode **21**.

VI. Particle flow

Further consideration of the process involved in the present invention requires investigation of the space-charge optics and the particle flow. The laws by which charged particles move from an emitter to a collector without regard to the direction of voltage between electrodes have been described by Langmuir and Blodgett ("Physical Review," vol. 24, No. 1, pp. 49–59, June 1924). That particular derivation was made to calculate the currents limited by space-charge between concentric spheres (either electron or ion but not in the presence of each other). For this invention, however, bi-polar charges exist within the spherical electrodes, and the Poisson's equation becomes:

$$\frac{d^2V}{dr^2}+\frac{2}{r}\left(\frac{dV}{dr}\right)=4\pi(\rho_e-\rho_i) \tag{10}$$

where V is the potential at any radius r, and ρ_e and ρ_i are the electron and ion volumetric space-charge densities.

Equation 10, together with the energy equations

$$\tfrac{1}{2}M_e v_e^2=eV, \text{ and } \tfrac{1}{2}M_i v_i^2=e(V_b-V)$$

where M is the mass of the charged particle, e the charge of the electron, v the velocity of the charged particle at any potential V, and b is the point of ion entry (which in this invention is considered to be the anode since most of the charged particles are assumed to be formed at or very near to their respective electrodes); and the density, charge and velocity relationships

$$J_e=\rho_e v_e, \text{ and } J_i=\rho_i v_i$$

(where J is the charge of the space-charge) are sufficient to determine all the relations involved in the electron and ion space-charge flows; i.e., all motions are assumed to be radial in this basic determination.

By following the general approach employed by Langmuir in a later paper, "The Interaction of Electron and Positive Ion Space Charges in Cathode Sheaths," ("Physical Review," vol. 33, page 954, June 1929), Equation 10 reduces to

$$3\mu\frac{d^2\mu}{d\gamma^2}+\left(\frac{d\mu}{d\gamma}\right)^2+3\mu\left(\frac{d\mu}{d\gamma}\right)=1-\gamma\left[\frac{\mu^{4/3}}{\mu_b{}^{4/3}-\mu^{4/3}}\right]^{1/2} \tag{11}$$

where

$$\lambda=\frac{I_i}{I_e}\sqrt{\frac{M_i}{M_e}} \tag{12}$$

I_i=the circulatory ion current;
I_e=the circulatory electron current in the presence of ions;
$\gamma=ln(r/r_0)$, (r_0 being the radius of the emitting surface); and
$\mu=f(\gamma)$, (corresponding to the α of Langmuir and Blodgett and becomes α when λ equals zero). In this ideal treatment μ_b is taken at the anode and is thus a constant.

A quantity similar to λ was used by Langmuir in his June 1929 referenced paper which he called α. He showed that the potential gradient at the surface of the anode was proportional to $(1-\alpha)^{1/2}$ and so became imaginary if $\alpha>1$. In other words, if α were to become greater than unity, ions would be withdrawn faster than injected. While those calculations referred to a plane-parallel discharge, the same limitation has been found to apply to the spherical concentric shells if the area used in evaluating the current density J from the total current I is taken to be the area of a surface four-fifths of the distance from the emitter to the collector. (See I. Langmuir and K. T. Compton, "Review of Modern Physics," Vol. III, No. 2, April 1931) where one is confronted with radial flow, however, λ may be larger than unity and still satisfy the boundary conditions.

Once I_e is selected, then λ and I_i are uniquely determined; the ratio of the radii is likewise uniquely determined.

It will be noted, from Equation 12, that when one is concerned with a fixed ratio of the radii of the virtual electrodes, λ has but one value and therefore becomes a constant. When λ is zero (no ion current present), Langmuir and Blodgett's α may be substituted for μ in Equation 11 and reduces to:

$$3\alpha\frac{d^2\alpha}{d\gamma^2}+\left(\frac{d\alpha}{d\gamma}\right)^2+3\alpha\left(\frac{d\alpha}{d\gamma}\right)=1 \tag{13}$$

which, as should be, is the Langmuir and Blodgett equation.

Spangenberg (book "Vacuum Tubes," 1st ed. 1948, § 8.4, p. 181) submits that the equation for the electron space-charge flow of current for concentric spherical electrodes in the absence of ions is:

$$I_0=\frac{29.34\times10^{-6}\times V^{3/2}}{\alpha^2} \tag{14}$$

where V is the potential difference between the spherical electrodes and α is a function of $\lambda=ln\ (r/r_0)$ given by the Maclaurin series:

$$\alpha=\gamma-0.3\gamma^2+0.075\gamma^3-0.0013\gamma^4+\ .\ .\ . \tag{14a}$$

The values for α are valid whether the cathode is external or internal and can be found in tabular form in Table II of the referenced Langmuir and Blodgett paper. Two functions designated as α^2 and $(-\alpha)^2$ are listed. The first applies to the case where the voltage V is evaluated at a point P outside the electron emitting electrode; the second where P is inside that source.

Germane to this invention, Langmuir's logic may be extended into the determination of electron and ion circulatory currents in the present of each other. As was the case for the Langmuir and Blodgett Equation 13, Equation 11 probably cannot be integrated directly, but a solution was obtained in the same manner as used by Langmuir and Blodgett. The electron circulatory current in the presence of ions took the form:

$$I_e=\frac{29.34\times10^{-6}\times V^{3/2}}{\mu^2} \tag{15}$$

The values for μ being obtained by expanding the Taylor's series:

(15a)

$$\mu=f(\gamma)=\gamma_0+\frac{\gamma+\gamma_0}{1}f'(\gamma_0)+\frac{(\gamma-\gamma_0)^2}{2}f''(\gamma_0)+\frac{(\gamma+\gamma_0)^3}{3}f'''(\gamma_0)-\ .\ .\ .$$

Equation 15*a* is expanded near zero to avoid infinite terms in the higher derivatives.

It is apparent from Equation 15 that the electron circulatory current I_e is independent of the actual sizes of the spheres since the radii enter only as a ratio.

Knowing the value of λ and the circulatory electron current from Equation 12, circulatory ion current I_i can be determined. Thus:

$$I_i = I_e \times \lambda \times \sqrt{\frac{M_e}{M_i}} = \frac{29.34 \times 10^{-6} \times V^{3/2}}{(-\mu)^2 \sqrt{\frac{M_e}{M_i}}} \lambda \tag{16}$$

It was at this point in the solution of the Poisson equation for bi-polar charges in a spherical geometry that I was led to conclude, and which was later verified by experimentation, that a phenomenon of alternating virtual cathodes and anodes could be made to exist in the volume enclosed by the inner hollow electrode of a fusor. Furthermore, to satisfy the Poisson's equation, λ would have to be greater than unity when a virtual cathode enclosed a virtual anode, such as shown by r_{c_1} and r_{a_1} (FIG 3). A "singularity" or mathematical discontinuity appears to exist at the virtual anode. Likewise, such a "singularity" appears to exist at the virtual cathode r_{c_2}, enclosed by the virtual anode r_{a_1}. In this type of system "a space-charge saturated current cannot be produced on the side of an emitting surface which radiates outwardly." The radial potential distribution for the fusor of this invention is shown in FIG. *5a*. That such "singularities" do exist in the fusor of this invention can be likened to the case of a charge uniformly distributed over an imaginary spherical shell.

If one assumes that a positive charge Q is uniformly distributed over an imaginary spherical shell of radius r_1, Gauss' law for electrostatic charges may be applied to calculate the field intensity (E) and the potential (V) at any radius r inside and outside of the radius r_{a_1} (FIG. 5). Additionally, the surface charge density ρ_s may be calculated as a function of the radial distance r. (See Sec. 1–20, Chapter 1, Part I, of "Electromagnetics" by John D. Kraus, McGraw–Hill Electrical and Electronics Engineering Series, 1st Ed., 1953.) It is found that the field intensity E is zero (in the absence of electric charges) for any radius inside the shell and the absolute potential at a radius outside the shell is given by

$$V = \frac{Q}{4\pi r \xi_0} \tag{17}$$

where Q is the positive charge in coulombs; and ξ_0 is the permittivity of air in farads per meter. Since the field intensity is zero inside the shell, the potential within the shell will be constant. The surface density ρ_s is zero everywhere except at the radius of the shell where it has the value

$$\rho_s = \frac{Q}{4\pi r_1^2} \tag{18}$$

The variation of E, V and ρ_s is shown by FIG. 6, curves (*a*), (*b*) and (*c*).

The similarity of the radial potential gradients of FIGS. *5a* and *6b* is marked. Inasmuch as the gradient (dV/dr) at r_1 (FIG. 6) and r_{a_1} (FIG. *5a*) is zero, and a condition for space-charge saturation at r_{a_1} is defined by an infinitely thin spherical shell at that radius, it is reasonable to assume that Equations 17 and 18 can be applied to the treatment of a radial potential distribution such as shown by FIG. *5a*, even though that field is not produced by bound charges. It is helpful to identify the referenced emitting surfaces by subscripts (cathode *c* and numeral or anode *a* and numeral) which produced the circulating current (electron or ion) being calculated.

Since the circulatory currents through all virtual electrodes have constant values for all radii between the limits of travel thereof, it becomes fundamental that:

$$\frac{I_e}{I_o} = k^2 \tag{19}$$

where k^2 is a constant independent of the voltages at any radii. Using Equations 14 and 15, Equation 19 may be written in the form:

$$k^2 = \frac{\dfrac{29.34 \times 10^{-6} \times V_a^{3/2}}{-\mu_c^2}}{\dfrac{29.34 \times 10^{-6} \times V_a^{3/2}}{-\alpha_c^2}} = \frac{-\alpha_c^2}{-\mu_c^2} \tag{20}$$

when the real cathode *c* is the emitting surface.

Langmuir's Equation 12, et seq., in his paper of June, 1929, teaches a method for computing values of I_e/I_o for plane-parallel electrodes for any values of his α (which corresponds to my λ for the spherical-electrode geometry).

When the ratio of the radii r_{a_1}/r_{c_1} (FIG. 3) approaches unity, the spherical geometry approaches the plane-parallel geometry so closely that the potential gradient at r_{c_1} becomes zero and I_e/I_o (and k^2) takes the same value as Langmuir's for α equal to unity, which is 1.8605. This means that the electron circulatory current in the presence of unlimited ions will be 1.8605 times that for the same applied potential in the absence of ions.

When λ becomes zero, i.e., no ion current present, I_e/I_o again is the same as Langmuir's α and I_e/I_o (and k^2) which is unity.

Thus, one observes that with the limits for Langmuir's α and my λ being identical, it holds that α and λ will be the same for intermediate values. Accordingly, I have computed and plotted in FIG. 7 the values of I_e/I_o for various values of λ so as to permit obtaining any intermediate values readily.

Experimentally, one may apply a desired potential between the real anode **20** at radius r_a and the real cathode **21** at radius r_c (FIG. 3) and measure the current I_o therebetween. Ions from the ion sources are then injected and measurements of the resulting currents I_e recorded. The ratios of I_e/I_o may then be calculated and the corresponding values for λ obtained from FIG. 7.

Thus, having values for I_e/I_o (or k^2), I_e and λ, one may compute values for the corresponding I_i $(-\alpha)^2$, and $(-\mu)^2$, keeping in mind that the virtual electrodes cannot emit outwardly and only the negative values for α and μ are valid. With these data, one has the means for obtaining the radial potential distribution.

The radius of the virtual anode r_{a_1} (FIG. *5a*) is generally known quite accurately from experimental data of a variety of kinds and largely by heuristic reasoning based on those data. The actual value of r_{a_1} (and the resulting ratio r_{c_1}/r_{a_1}) depends upon the total energy losses, which will be taken up later, required to maintain the desired poissor and the magnitude of the high-energy ion current which flows through (or into) the real cathode **21** (radius r_c). The approximate values for r_{a_1} have been determined visually for experimental fusors.

In the design of a working embodiment of a fusor, it is essential that the volume enclosed by the innermost virtual cathode, such as **30** at radius r_{c_2} (FIG. *5a*) be adequate to confine a sufficient total number of fusion particles (at a volumetric density of unity fusion probability) to assure the generation of a useful amount of power. It has been found that if the ratio of the radii of the adjacent pair of virtual electrodes is much greater than 3, the inner virtual cathode may not form; if the ratio of radii is too small, the circulatory currents required to maintain the poissor become excessively large.

In an actual working embodiment of a fusor, the radii of the virtual anodes and cathodes can be computed, as well as the values of the currents and the radial potential distribution outside of the virtual cathode **30** at radius r_{c_2}. The radial potential within the aforementioned virtual cathode has not been computed because as the radii of the balance of the virtual electrode system become much samller, errors in ion and electron optics begin to reveal themselves to the extent that it is not known whether or not the system continues to repeat itself. Since fusion does occur in the small volume in the fusor's center, the space-charge conditions prevailing therein have therefore been determined by logic and heuristic reasoning.

In FIG. 3 is illustrated diagrammatically one embodiment of this invention consisting of an anode **20**, a cathode **21** and an ion gun **22**. Enclosed within the cathode **21** is shown a poissor with a virtual cathode **29** at a radius of r_{c_1}, a virtual anode **31** at a radius of r_{a_1}, a virtual cathode **30** at a radius of r_{c2}, and a vestigial virtual anode **32** at a radius of r_o. To understand the operation of the fusor, it is important to distinguish between the currents which flow through the apertures of the real cathode **21**, referred to herein as "mesh currents" (i_m), and the current which flows into the real cathode **21**, termed "cathode current" (i_c).

The ion "mesh current" (i_{im}) is produced by the ions:

(a) injected into the cathode **21** space from the ion guns;
(b) released by the anode **20** under bombardment by electrons and neutral gas molecules;
(c) created in the volume between the anode **20** and the cathode **21**; and,
(d) created by the ionization process within the volume r_{a_1} to r_{c_1}.

Those ions which originate on the anode **20** will be collected by the cathode **21**, or returned to the anode **20** after but one round trip; those few ions created on the inward side of the virtual anode **31** ($r \leqq r_{a_1}$) which have sufficient energy to penetrate therethrough will be collected by the anode **20** or the cathode **21** after only a few round trips; the other ions will oscillate from the virtual anode **31** through the cathode **21** apertures until collected by the cathode **21**. The potential of the virtual anode **31** will build up to that of the anode **20**.

The electron "mesh current" (i_{em}) which initially may be quite large and is extremely useful in the formation of the virtual electrode system, will become so small in operation as to be negligible. It is made up of those electrons emitted by the inner surface of the real cathode **21** and which flow through the cathode **21** apertures to the anode **20**.

The total mesh current through the cathode **21** apertures, therefore, is the algebraic sum of the ion mesh current and the electron mesh current. Thus,

$$i_m = i_{im} + i_{em} \tag{21}$$

The net cathode **21** current i_c is the algebraic sum of the ion current into, and the electron currents into and out of it. Ions flowing into and electrons flowing out of the cathode **21** as usual are positive currents to the cathode **21**. Thus,

$$i_c = i_{ic} + i_{e2c} - i_{e1c} + i_{ec}' \tag{22}$$

where i_{ic} is the ion current into the cathode; i_{e1c} is the electron current into the inside of the cathode; i_{e2c} is the electron current out of the inner surface of the cathode; and i_{ec}' is the electron current from the outside surface of the cathode to the anode.

The space current i_s into or out of the volume enclosed by the cathode **21** is the sum of the mesh current and the cathode **21** current, so

$$i_s = i_m + i_c \tag{23}$$

The general condition for an equilibrium potential field occurs when i_s becomes zero, as no charges are then being added or removed from the space. Accordingly,

$$i_m = i_c = 0 \tag{24}$$

and when i_c is zero, the power consumed by the device is a minimum.

It is the ion mesh current i_{im} into the central cathode **21** volume which maintains the density of the virtual anode **31**, and which causes any free charges therein to be oscillated radially. As the inward flow of ions continues, the positive potential at the virtual anode **31** increases until all the inward flow of ions is cancelled by the outward flow to the cathode **21**. The net ion mesh current then becomes zero. Neglecting the minute electron mesh current i_{em}, when all the electrons that are emitted from the inside of the cathode **21**, as well as all of the ions and electrons generated within the cathode **21** volume, return to the cathode **21**, it is apparent from Equation 22 that only the electron current, i_{ec}', remains to flow to the anode **20**. Thus, for i_c to become zero, i_{ec}' must likewise be brought to zero. Such an equilibrium potential field can be obtained when there are sufficient ions reaching the anode **20** to compensate for i_{ec}'.

Those ions from the virtual anode **31** which have energies equivalent to or greater than V_a will reach the anode **20** and remove an equal or greater number of electrons therefrom. With a sufficient number of such ions reaching the anode **20**, the component of cathode **20** current, i_{ec}' can be reduced to zero.

In the disclosure thus far, a space-charge saturation of the cathode volume has been assumed. The ions which are created near the virtual anode **31** ($r \leqq r_{a_1}$), where the ionization process is a maximum, have energies approaching eV_{a_1}. They traverse the inner virtual cathode **30** and the vestigial virtual anode **32** at fusion-reacting energies; this is an essential operating condition. The bulk of the ions which make up the ion mesh current i_{im} are created in the volume outside the virtual anode **31** ($r \geqq r_{a_1}$) and, like those ions from the ion guns **22** and the anode **20**, are ultimately collected by the cathode **21**; thus, if space-charge saturation could exist in this region, it would produce such an extremely large energy loss that nuclear-fusion reactions could not obtain. Fortunately, as previously shown, ion space-charge saturation cannot exist in this region, and operating conditions are maintained such that the ion circulatory current is just adequate to assure a virtual anode **31** of the desired size. Thus, the ideal radial potential distribution for the device of this invention (sometimes referred to herein as a "fusor") is as shown in FIG. 5*a* where the poissor is maintained by ion space-charge saturation in the volume $r \leqq r_{a_1}$ and a non-space charge (dissymmetrical) field exists in the cathode **21** volume where r is greater than r_{a_1}. λ, therefore, has the value which gives ion space-charge saturation only in the region adjacent to the radiating surface of the virtual anode **31** where the potential gradient is zero; electron space-charge saturation obtains in the region just inside of r_{c_2}.

Within a virtual anode **31** (FIG. 5*a*), each positive charge must be matched by an electron. Most of the flux lines from the ions at a radius $r \leqq r_{a_1}$ terminate in the virtual cathode **30**; where $r \geqq r_{a_1}$, most of the flux lines terminate in the virtual cathode **29**. All the charged particles in the cathode **21** volume are free to move and are in oscillation. The virtual anode **31** at r_{a_1}, the locus of maximum ion density, has the potential practically equivalent to V_a, and very few ions are formed inside that virtual anode with energies greater than eV_{a_1}. Thus, to maintain the potential V_{a_1}, it is only necessary that there be an equal number of flux lines from the inner of r_{a_1} to r_{c_2} as there are outward to r_{c_1} (FIG. 5*a*). Ions with lesser energies than eV_{a_1} will reach their reversal loci at radii greater than r_{a_1} when $r \geqq r_{a_1}$ or less than r_{a_1} when $r \leqq r_{a_1}$ and those ion densities will be less than at r_{a_1}. If a few ions are generated inside of r_{a_1} with energies greater than eV_{a_1}, they will pass through the virtual anode **31** and fall to the cathode **21**, and in some instances to the anode **20**; they do not contribute to the ion circulatory current. The virtual anode **31** thus acts as an effective hi-pass ion filter for ions with energies greater than eV_{a_1}. Inside the virtual anode **31** where $r \leqq r_{a_1}$, the ions travel slowly for a relatively large portion of their radial paths as they approach their respective reversal loci; the opposite is true outside the radius r_{a_1} where the ions are decelerated rapidly as they approach r_{a_1}, giving up their energies within a very short distance from r_{a_1}.

The radial potential V_r is a function of the radius r and the time t; i.e., $V_r=f(r,t)$. The buildup of the poissor inside the radius r_{a_1}, together with the creation of the asymmetrical field outward from r_{a_1}, is shown diagrammatically by FIG. 8. The anode **20** and the cathode **21** initially are at ground potential as shown. If a negative potential of V'_c (curve *a*, FIG. 8) of approximately −30 kv. is applied to cathode **21**, and ions from the ion guns are injected into the cathode **21** volume concurrently, they begin to charge that volume positively. This charge will increase until the potential at some internal radius r_{a_1} is sufficient to return the ions to the cathode **21** at the same rate at which they enter the cathodic **21** volume. This equilibrium may be expressed by the relation

$$i_{\text{im}}=i_{\text{ic}} \tag{25}$$

As soon as the potential inside the cathode **21** becomes positive, electrons emitted from the inner surface of cathode **21** will be accelerated toward and oscillate through the central volume and quickly establish virtual cathodes at r_{c_1} and r_{c_2}. With the virtual cathodes formed, the position of the virtual anode between them is determined. The equilibrium radius and the potential of the virtual anode at r_{a_1} requires a somewhat longer buildup time than the formation of the virtual cathodes at r_{c_1} and r_{c_2} because of the longer ion transit time.

When the negative potential on the cathode **21** is abruptly increased from V_c' to $V'_c{}'$ to $V'_c{}''$, similar sequences of events occur. Each of the subsequent equilibrium radial potential gradients is shown by curves *b* and *c* of FIG. 8.

To determine the position of the virtual electrodes, it is only necessary to establish the radial density distribution of electrons and ions. The radial potential distribution already has been so calculated. The virtual anode locus will lie close to the surface where the ion density is the greatest. The virtual cathodes will lie at the termini of the electron paths where the electron densities are the highest.

A practical embodiment of this invention by which the aforesaid conditions for a self-sustaining nuclear-fusion reaction can be produced is shown diagrammatically by FIG. 9. A spherical anode **20** of radius r_a encloses dual concentric cathodes **21** and **36** of radii r_c and r_c', respectively, and ion guns **22** and **22***a* mounted on the outside of anode **20**. The concentric cathodes **21** and **36**, which are constructed of an electron-emitting material such as stainless steel, molybdenum or the like, and which have an openness of about 70% by virtue of spherically spaced, registered apertures **37** and **38**, are supported within the anode **20** by suitable insulators (not shown). The concentricity of the cathodes **21** and **36** is maintained by suitable insulators therebetween (not shown). Attached to the outer cathode **36** on the axis passing through the ion gun **22** is a conical sleeve **40** through which the intense pencil-like ion beam is focused. Suitable connections are made between the unidirectional power supply **25** and the electrodes through leads **23**, **24**, and **42**. The anode **20** is maintained at or near ground potential as shown, while negative potentials are applied to the cathodes **21** and **36** from a supply **43**, with the outer being more negative than the inner.

In operation, most of the ions from the ion guns **22** and **22***a* are utilized to establish the initial virtual anode in the central volume of cathode **21** as previously described. Electrons from cathode **21** are prevented from reaching the anode **20** by the negatively biased outer cathode **36**. The early removal of ions from the non-space-charge saturated field is greatly enhanced by the second cathode **36**, and only those positive charges with energies greater than V_a have any likelihood of avoiding capture on their first outward pass from the virtual anode **31** (FIG. 5*a*). Ions captured by the outer cathode **36** (FIG. 9), will create electrons therefrom which either will enter the cathodic space or be returned by the outermost virtual cathode.

VII. *Losses*

In order to form and sustain a radial-potential distribution such as is shown in FIG. 5*a*, it is first necessary to compensate for all losses. For a typical small fusor, these losses, which represent about 10% of the total power created, in their order of importance and magnitude are:

(1) Heat loss—7%
(2) Charge interchange—2%
(3) Power required to create electrons—⅔ of 1%
(4) Bremsstrahlung—⅓ of 1%

Heat loss.—In the center of an inner virtual cathode in a poissor, the ions from the inner side of the adjacent virtual anode are traversing the center from all directions. As they pass near other ions, they will experience some deflection which will result in small deviations from radial paths and thus they will appear to be in random motion. This is the equivalent of a very high apparent temperature, about 1.6 ×10⁹ °K. for 100 kev. or about 11,600 °K./c.v. (Maxwell-Boltzman constant). This apparent temperature reduces to about 2×10^6 degrees K. in a distance of a few millimeters from the center. Any neutral atom which passes through this central region will be heated to an extremely high temperature. It will experience a cryogenic pumping action that will expel it to one of the real electrodes where, upon impact, it will give up its kinetic energy (heat), penetrate the surface to a depth determined by its kinetic energy, then diffuse out in a random direction following the cosine law. There is very little likelihood of its again reaching the center as it will remain in the vicinity of the electrode until ionization takes place.

It becomes very serious when too many high-energy neutral atoms are intercepted by the cathode as the cooling thereof is most difficult. On the other hand, cooling of the anode is relatively easy. The cooling of the cathode may be accomplished by conduction through its electrical connections to the power supply. The size of the cathode does affect the cooling problem, as increasing the size reduces the heating per unit area by the ratio of $1/r^2$ since the circulating currents are independent of the radii of the spheres.

Rutherford's scattering equation shows how the neutron count can be made to increase with an increase in applied voltage, for: the current rises by the three-halves power; and the particle density may be increased as it is proportional to four times the energy (or voltage) squared. Accordingly, the heat loss will decrease with an increase in voltage as there will be less scattering. For example, refer to FIG. 10, which shows a typical neutron cross-section curve for an equal mixture of deuterium and tritium. The operating points *a* and *b* are for the same fusion cross-section (σ_f), but from the point of view of the heat losses, *b* provides for more efficient performance, for:

$$\frac{N_{\frac{\theta}{2}}}{N_o}=\frac{\pi\rho_c{}^4}{4w^2}\cot\theta \tag{26}$$

where

$$N_{\frac{\theta}{2}}$$

is the number of ions deflected by half angles; N_o is the total number of ions; and W is the energy ($mv.^2=2W$); ($(mv.^2)^2=4W^2$) which shows that the lower the voltage the greater the losses.

Charge interchange.—Ions travel relatively slowly within the radial thickness adjacent to the virtual anode due to the repelling forces of their like charges. Therefore, there is a fairly high probability that a charge interchange with a neutral atom may occur. This loss is discussed in my Patent No. 3,258,402, previously mentioned. This loss becomes sizeable if there are too many gas molecules present. The gas density (pressure) must be kept as low as is possible to maintain a high fusion probability. This affects the fusor's design characteristics. In practice, the fusor is operated at a neutral gas density of 3.535×10^{13} molecules or less, such that

ρ_n is the normal gas density of 2.687×10^{19} molecules/cc. at normal temperature (20° C.) and pressure (760 mm. of Hg); and

ρ_i the operating gas density, in ions per cc., is

$$\frac{2.687\times10^{19}}{760\times10^{-3}}\times10^{-6}=3.535\times10^{13}\text{ ions/cc.}$$

at a working pressure of one micron (10^{-3} mm. Hg).

As the power level of a fusor is increased, more ion current will be required from the ion guns, which in turn will increase the radius of the virtual anode **31** (FIG. *5a*). This will mean a larger volume which, for ion space-charge saturation, will result in an increase of the total number of the ions contained therein. The greater power input (ions) will increase the power loss, thus again increasing the radius of the virtual anode until equilibrium is reached where the power input equals the power dissipated.

Bremsstrahlung.—When high-energy electrons are deflected on their passage through the virtual anode **31**, they radiate at right angles to their directions of motion. As the electrons have momentum which must be conserved, there will occur an equal and opposite reaction when an electron changes its direction of travel. Since these reactions take place after the electron changes its direction, they are non-radial. These non-radial electrons broaden the virtual cathode **30** with a movement toward the center **26**, and thus increase the electron temperatures. The so-called "radiation dampening" effect of the excess ions (positive nuclei) in the virtual anode tends to reduce the Bremsstrahlung losses to less than 1% of the power available in the virtual anode. With the value of the ion density in the virtual anode, the electron scattering can be computed by the well-known Rutherford formula for scattering.

VIII. *Fusion reactions*

The fusor, as shown diagrammatically in FIG. 9, is initially evacuated to a pressure of from 10^{-9} to 10^{-10} millimeters of mercury by means of a vacuum pump **44**, the anode **20** being the hermetically sealed envelope. Potentials are applied to the various electrodes as already explained and a fusion-reactive fuel, in the form of gas, is introduced into the ion guns **22**, **22*a*** from sources **45** and **45*a*** at a pressure of from 10^{-6} to 10^{-4} millimeters of mercury. This fuel gas is ionized by the guns **22**, **22*a*** and formed into ion beams directed diametrically toward center **26**. A poissor forms, as previously explained.

High energy ions oscillate through the region of the center **26** along diametral paths, terminating adjacent to the virtual anode **31** (FIG. *5a*). Other lower energy ions follow shorter diametral paths within the virtual anode **31** through the same region, thereby contributing to the density of ionic particles in the center. With the virtual anode **31** potential high enough (100 kv.), collisions of the high energy ions with others in the center **26** region will produce nuclear-fusion reactions.

There are a number of nuclear-fusion reactions which are possible. Fusion reactions of an exothermic nature will be specifically considered as one type of reaction which this invention seeks to attain. Power production by such reactions is theoretically proportional to both the amount of energy released per reaction and the number of reactions taking place per unit time. The number of reactions per unit time is obtained from the product of the nuclear cross-section, which expresses the probability for a specific nuclear reaction to occur, the number of ions in the center **26** region, and the number of projectile particles passing through this region from the anode **20** and the virtual anode **31** (FIG. *5a*) per unit time. The nuclear cross-section, or the probability that a nuclear reaction will occur, is a function of the velocity or energy of the interacting particles, which in this device is a function of the potential difference between the anode **20**, the virtual anode **31** and the center **26** (FIG. 3). From the above, it is clear that good power-producing reactions require a large nuclear cross-section and also a large amount of input energy.

One reaction which theoretically is outstanding in meeting the above requirement is the tritium reaction with deuterium. The nuclear equation for this process is:

(3) ${}_1D^2+{}_1T^3\rightarrow{}_2He^4$ (3.5 mev.)$+{}_0n^1$ (14.1 mev.)

This states that a triton plus a deuteron plus the sum of their kinetic energies results in a nuclear reaction whose products are helium 4, a neutron, and the sum of the excess binding energy and the kinetic energy possessed by the original trition and deuteron. The reaction energy released is 17.6 million electron volts (mev.) for the sample above. This value is large compared with the values for other possible reactions, which in most cases yield 3 or 4 mev. The nuclear cross-section for the reaction shown in Equation 3 peaks at a value of about 5×10^{-24} cm.^{2} for projectile energies of 100 kiloelectron volts (kev.). This cross-section value is about 10^2 times larger than that for most competing reactions when compared at the same projectile energies.

Additional possible reactions are the following:

(1) ${}_1D^2+{}_1D^2\rightarrow{}_2He^3$ (.82 mev.)$+{}_0n^1$ (2.45 mev.)

(2) ${}_1D^2+{}_1D^2\rightarrow{}_1T^3$ (1.01 mev.)$+{}_1p^1$ (3.02 mev.)

(4) ${}_1D^2+{}_2He^3\rightarrow{}_2He^4$ (3.6 mev.)$+{}_1p^1$ (14.7 mev.)

Reactions 1 and 2 have a lower value of released energy and a lower 100 kev. cross-section value than Reaction 3. Reaction 4 has about the same energy value but a lower 100 kev. cross-section value.

IX. *Fusion products in the discharge*

As already explained, when an external voltage is applied between the anode **20** and the cathode **21**, **36** (FIG. 9), a system of virtual anodes and cathodes (poissor) is formed within the cathodic space. The radial potential distribution of the poissor was shown in FIG. *5a*. It is within the minute volume enclosed by the virtual cathode **30**, where the ion density is the greatest and the energies (velocities) of the projectile ions a maximum, that the probability of fusion is the highest.

It was shown by Equations 1, 2, 3 and 4 that, using only six deuterons, it is possible to trigger four different nuclear-fusion reactions, and these reactions result in the creation of five new kinds of particles having a total energy of 43.2 million electron volts (mev.). Four of these five particles (${}_1p^1$, ${}_1T^3$, ${}_2He^3$ and ${}_2He^4$) are positively charged, and carry 26.65 mev.; the fifth is a neutral particle, the neutron, and the two produced by the two reactions carry 16.55 mev. There are two important aspects of this energy distribution between the charged and uncharged particles. Firstly, the neutrons will escape from the reacting system and dissipate their energy elsewhere as heat, because being uncharged, they easily pass through material walls. Only the charged particles will be retained within the reacting region and be available to compensate for energy losses (radiation, recombination, etc.) and to sustain the nuclear-fusion reactions. Secondly, it is only the energy of the charged particles, which represents 64% of the energy released by the four reactions, that is available to be converted directly into electrical power. It should be noted that only those ions which are created by the fusion reaction will have sufficient energy to produce electrical energy.

All of the particles formed by the nuclear-fusion reaction are ejected radially outward from the reaction volume with the high energies shown by Equations 1 through 4. These energies (velocities) are more than adequate to propel them through the virtual anode **31** (FIG. 5*a*). Under the influence of the real cathode **21, 36** (FIG. 9), they will be accelerated on their outward journey until passing through the cathode apertures **37, 38**, where they will be decelerated by the anodic field and either brought to rest short of the anode **20** or impact the anode. If particles do not reach the anode **20**, they will then reverse their direction of travel and go into oscillation through the center. Those which do strike the anode **20** will dissipate their remaining energies as heat and at the same time deposit their charges on the anode. A few particles may strike the cathode and be captured, with an accompanying release of secondary electrons.

With deuterium only in the fusor, for two D—D reactions (Equations 2 and 3) will take place at essentially equal rates. The positively charged products of these reactions which go into oscillation increase the ion circulatory current, thus increasing the ion density in the reaction space and hence the probability of fusion. The oscillating reactive particles ($_1T^3$ and $_2He^3$) may fuse with deuterons to produce the reactions shown by Equations 1 and 4, or may experience scattering, capture or recombination with electrons and become neutral atoms. The non-fusionable particles ($_1p^1$ and $_2He^4$) contribute to the fusion process only by the creation of fusion-reactive ions through the capture of electrons from fuel-gas atoms and by their contribution to the space-charge; ultimately, they will become neutral gas atoms. The neutral gas atoms will drift toward the electrode walls, where eventually they will be scavenged from the reaction system by the vacuum pump 44 (FIG. 9).

It has been stated that some of the charged particles will reach the real anode **20** when ejected by the nuclear-fusion reactions. When this occurs, the particles remove enough electrons from the anode **20** to neutralize their positive charges and form gas atoms. This is the equivalent of producing a current which flows from the anode **20** to the battery **25** (FIG. 9) (power supply). In other words, the charged particles have been coverted directly into electrical energy. This is one of the unique features of this invention.

Insertion of a suitable resistor **46** (FIG. 9) in series with the power lead **24** becomes a means for coupling the converted electrical power to an external load. A switch **47** is used to connect selectively this resistor **46** into the series arrangement.

It will be seen from Equations 1 through 4 that as many positive charges enter the fusion region as are removed therefrom. In other words, nuclear charges are conserved. What the fusion reactions do accomplish is the formation of new particles with the release of the excess binding energy of the original ions and, as the original energy must be conserved, the excess is applied to the new particles. Accordingly, the new particles leave the reaction volume at extremely high velocities. The replacement ions which enter the reaction volume do so at the comparatively low velocities of the order of 100 to 200 kev. Thus, there is an extremely short period when the potential in the center is less than prior to the fusion reaction which, in effect, tends momentarily to increase the negative potential of the virtual cathode **30** as well as decrease the virtual anode **31**, and there is an associated increase in the electron current. This effect produces an increase in the radii of the virtual electrodes until the original potential of the vestigial anode **32** (FIG. 5*a*) can be restored. Thus, there is a periodic expanding and contracting of the poissor volume by the very high frequency oscillation of the inertially contained particles.

When the fusion reaction commences, there will be more positive charges leaving the center than flowing in and this condition will continue until steady state is reached. This would tend to develop what might be termed a "potential well" (more negative potential) at the virtual cathode **30**. Such a condition could not exist, as current would then flow from the real cathode **21, 36** (FIG. 10) to the virtual cathode **30**. Accordingly, the virtual cathode **30** must be returned to the real cathode potential within an extremely short period of time. This is accomplished by an equivalent increase in the potential of the virtual anode **31**. The loss of positively charged particles from the center produces a positive bias on the virtual cathode **30** which is equivalent to an increase in the potential of the virtual anode **31**. As these increases are cumulative until the steady state condition is produced, it is seen that the virtual anode **31** (FIG. 5*a*) reaches the potential of the real anode **20**.

The positively charged particles formed by the fusion reaction perform work against the field of the virtual anode **31** as they pass through it. In so doing, their velocities are reduced somewhat, thus increasing the field and contributing to the potential of the virtual anode. They are then accelerated by the cathode, regaining energy.

It is the potential of the virtual cathode **30** (FIG. 3) which contributes to the energy of the positively charged particles which oscillate through the center **26**. As the energies of the reacting particles increase, within the resonance limits of the nuclear-fusion cross-section, the probability of fusion increases. Electrons which are created within the virtual anode **31** are ejected radially outwardly with sufficient energy to overcome the repelling field of the real cathode.

If one were to lose control of the input density of the fuel-gas atoms, it might appear that the process of building up the potential of the virtual anode **31** could continue unabated and might well result in a catastrophic accident. Such is not the case, however, as there are "built-in" safety processes which act to prevent such a build-up. The principal control is the cross-section resonance phenomenon which occurs in nuclear reactions. The cross-section curves for D—D (total), D—T and D—HE^3 reactions, such as contained in "Physical Review," vol. 88, p. 468, 1952, by Connor, Bonner and Smith, and also "Physical Review," vol. 88, p. 473, 1952, by the same authors, show that the D—T curve exhibits a maximum at an energy of 110 kilo-electron volts (kev.), where it falls off sharply with increasing deuteron energy. In the same energy range, the D—He^3 cross-sections are appreciably less than the D—D (total) and the D—T values, but the curve is rising rapidly with increasing deuteron energy and it crosses the D—D (total) curve at 120 kev.; it approaches the D—T curve at 500 kev., its peak, and then falls off rapidly. For example, in the range of deuteron energies from 120 to 200 kev., the D—T cross-sections decrease 1 barn (10^{-24} cm.^{2}) while the D—D (total) and the D—He^3 cross-sections increase only about 0.5 barn, an overall decrease of approximately 1 barn. After the D—He^3 cross-sections pass their maximum at 500 kev., the decrease in the overall cross-sections is much more pronounced. Thus, it is apparent that the build-up in the potential of the virtual anode will be checked at deuteron energies greater than about 150 to 200 kev.

Another built-in safety process which assists in preventing a "run-away" by the so-called "potential well" is the widening of the negative potential sheath (virtual cathode **30**) (FIG. 5*a*), as the radius is changed by the oscillating particles, which produces a decrease in the fusion cross-sections.

The conversion of the positively charged particles into electrical energy at the anode has been touched upon briefly. This phase will now be covered in some detail. In order to prevent the over-heating of the anode, it is highly desirable that most of the particle energy be given up to the decelerating virtual and real anode fields. The particles would reach the anode **20** with very much less than their original energies and thus dissipate less heat to it with a significant increase in the overall efficiency. The ideal situation would permit the charges to reach the anode **20** (FIG. 9) with little or no remaining energy, deposit their charges and drift away as neutral gas atoms. Obviously, with such a wide range of energies, 0.82 to

14.7 mev., this condition cannot be achieved. Therefore, one may envision two different operating situations; namely, (a) be satisfied with the maximum electrical conversion that can be obtained with the minimum heating of the anode **20**, or, (b) operate the fusor as a heat machine to convert heat and charged particles into the maximum amount of electric power.

In the first situation, it becomes necessary to restrict, as nearly as possible, the fusion reactions to those of Equations 2 and 3, where the energies range from 0.8 to 3.02 mev., and to operate the anode at a potential which will produce a deceleration of the 0.8 mev. particles such that they arrive at the anode **20** with just sufficient energy to deposit their charges. The 3.02 mev. particles under this condition will impact the anode **20** and convert its remaining energy into heat. Inasmuch as approximately 50% of the D—D reactions will follow the proton branch, it is not possible to eliminate that higher energy particle. The reactions of Equations 1 and 4 may be reduced appreciably by operating the fusor at a lower than normal gas density, thereby removing the neutral helium-three and tritium atoms by the use of a large volume vacuum pump **44** before they have an opportunity to fuse.

In direct contrast, if the device is to be operated as a heat generator, the D—T and D—He^3 reactions must be encouraged. Since the contribution of the D—T and D—He^3 reactions could be quite significant in the direct conversion to electricity, it might prove advantageous in some applications to produce tritium by bombarding lithium-six with the neutrons:

$$(27)\qquad {}_3Li^6+{}_0n^1\rightarrow{}_2He^4+{}_1T^3+4.6\text{ mev.}$$

and then utilize the tritium as a fuel gas.

If enough positively charged particles can be made to reach the anode **20** to reverse the current flow from the battery **25**, it then becomes possible to remove the applied anode (cathode) voltage **25** while continuing the nuclear-fusion reactions. If I and V_a are the measured current and anode voltage before fusion, then after fusion commences the input power in watts will be

$$(28)\qquad W=V_a\times\left[I-\langle F\rangle e(A-B)\right]$$

where $\langle F\rangle$ is the fusion expectancy; e is the electric charge; A is the interception factor of the positively charged particles by the anode; and B is the interception factor of the positively charged particles by the cathode. Since the cathode **21, 36** is almost pervious to positively charged particles, A will be very much greater than B and when the value of

$$\left[-\langle F\rangle e(A-B)\right]$$

becomes greater than $I(V_a)$, the fusor will become truly self-sustaining. This condition will be reached without the aid of an external load. To remove electrical energy in excess of that required to drive the fusor, it only becomes necessary to add an external load **46** such as shown in FIG. 9.

Working embodiment

A working embodiment of this invention as shown in FIG. 9 is illustrated in substantial detail in FIGS. 11 through 22. In these figures, like numerals indicate like parts. The anode **20** is of spherical construction, being fabricated of two hemispherical shells of stainless steel hermetically sealed together at the equators by means of suitable annular sealing flanges **47***a*. Concentrically positioned inside the anode **20** are the two cathode shells **36** and **21**, respectively, which are also assembled of hemispherical shells of stainless steel. The means for supporting these electrodes concentrically will be described in detail hereinafter.

Eight ion guns **22, 22***a* are mounted on the exterior of the anode **20** in spherically spaced and diametrically aligned relationship, these guns all having beam axes which intersect at the center **26** of the fusor. The precise location of these ion guns **22, 22***a* is explained in connection with the spherical diagrams of FIGS. 18*a* and 18*b* which show the angular relationship therebetween. Each of the ion guns is indicated by a circle with a center dot indicating the spot at which the gun axis intersects a spherical surface defined by the anode **20**. FIG. 18*a* illustrates a spherical surface corresponding to the anode and cathode shells with the plane of the drawing being the same as the cross-sectional plane of FIG. 11. This latter plane includes the north and south poles of the sphere. The line **47***b* indicates the equatorial plane at right angles to the plane of the drawing. In FIG. 11, this equatorial plane would pass midway between the annular flanges **47***a*. The guns **22** and **22***a* are located in the planes spaced 45° from the equatorial plane **47***b* as shown, these planes passing through the tube center **26** and being rotated about the equatorial diameter which is perpendicular to the plane of the drawing. As shown in FIG. 18*b*, which is a right angle projection of the spherical surface of FIG. 18*a*, there are four such guns **22** spaced 90° apart on the spherical surface and on the same meridian. In terms of angular displacement, these guns are indicated as lying on the 0°, 90°, 180° and 270° lines. Within each plane containing guns, each gun center is at the intersection of a radius 45° above the equator and the spherical surface, certain of the radii lying in the plane of FIG. 18*a*.

Four ion guns **22** are so located in the upper or northern hemisphere of the sphere while four other guns **22***a* are located allochirally in the southern hemisphere.

The apertures **37** and **38** in the cathode shells **21** and **36**, respectively, are in twelve registered pairs, each pair **37** and **38** being diagrammatically indicated by an X mark which is assigned numeral **48** in FIGS. 18*a* and 18*b*. The locations of the ion guns and the apertures **48** are indicated as being on the same spherical surface for showing the angular relation therebetween. There are four screen aperture pairs **48** on the equator as shown in FIG. 18*b* at the 0°, 90°, 180° and 270° lines. Planes intersecting the north and south poles which are spaced from each other by 90° contain the remaining aperture pairs **48**, these planes being spaced 45° from the 0°–180° plane which includes the north and south poles also. In these individual 90° planes, on a radius at an angle of 35°16′ with respect to the equatorial plane **47***b*, lie the remaining aperture pairs **48**. The spherical surface containing the aperture pairs **48** may be regarded as that of one of the cathode shells **21** and **36**.

With the equators of the cathode and anode shells lying in the same equatorial plane, the aperture pairs **48** are thus spherically offset in a regular angular pattern from the ion guns **22** and **22***a*.

The anode **20** shell, as well as the cathode shells **21** and **36**, are supported in position by a tubular mounting assembly indicated generally by the numeral **49**. This mounting assembly includes a stainless steel pipe section **50** perimetrically welded at one end to an opening **51** in the anode shell **20**. Coaxially and hermetically secured to the opposite end of the tube **50** is a larger diameter supporting tube or pipe section **52**. Inside this larger tube **52** is a smaller diameter sleeve **53** having a sliding fit therewith, the upper end portion of sleeve **53** being secured to the radial flange **54** which joins the two pipe sections **50** and **52**.

At the bottom end of the sleeve **53** is coaxially secured a mounting ring **55** from which depends four metal posts **56** spaced 90° apart around the axis of the pipe section **52**. A metal disc **57** is coaxially secured to the bottom ends of the posts **56** by means of suitable screws **58**, this disc **57** having secured to the central portion thereof a ceramic post **58***a*. This post **58***a* is coaxially positioned inside the pipe section **52** as well as the smaller pipe section 50 by means of the mounting sleeve, rings and posts just described.

Secured to the upper end of the post 58*a* and coaxially extending thereabove is a metal post 59 having threadedly connected thereto a disc-like mounting stud 60 which is welded into an opening 61 in the outer cathode shell 36. Abutting against the flat surface of this stud 60 is a ceramic or the like spacer 62 having a boss 63 intimately fitting into a locating aperture 64 in the inner cathode shell 21. The spacer 62 is sandwiched between the two shells 21 and 36, thereby determining the spacing therebetween.

The post 59 is of such length with respect to the pipe section 50, for example, as to position the two cathode shells 21 and 36 concentrically inside the anode shell 20. This post 59 may be regarded as coinciding with the south poles of the cathode and anode shells.

At the north poles of these shells is located further supporting structure as well as a terminal assembly for connecting the operating voltages to the electrodes. This assembly includes an annular spacer 65 of suitable insulating material, such as boron nitride, positioned between the two shells 21 and 36 so as to determine the spacing therebetween. This spacing is the same as that between the south poles. Coaxially secured inside this spacer 65 is a conductive terminal button 66 which is intimately conductively fitted into a companion aperture in the shell 21. This aperture coincides with the north pole of the shell.

Telescoped over an upwardly projecting portion 67 of the spacer 65 is an elongated tubular element or conductor 68 which intimately fits into and makes conductive contact with an aperture 69 in the outer shell 36.

This conductor 68 passes diametrically outwardly through the relatively large insulating aperture 70 in the anode 20 in spaced relation therewith, this spacing being large enough to provide insulation at the high voltage at which the fusor is operated. A conductive tubular assembly 71 is rigidly and hermetically sealed to the exterior of the anode 20 in registry with the aperture 70 and extends coaxially outwardly with respect to the conductor 68. At the upper end of this assembly 71 is secured a relatively long, cylindrically shaped insulator 72 (FIG. 12) which has secured to the upper end thereof a conductive terminal assembly 73. This terminal assembly 73 is provided with a suitable connection terminal 74 by means of which cathode bias from the battery 43 may be connected to a wire 75 which extends coaxially through the conductor 68 and connects to the terminal button 66. This tubular assembly 71, 72 and 73 which coaxially surrounds the conductor 68 is hermetically sealed such that the space between the conductor 68 and the assembly 71, 72 and 73 may be evacuated and held at the same pressure as the interior of the anode 20.

Inasmuch as high operating potentials prevail between the conductor 68 and the outer tubular assembly 71, 72 and 73, suitable corona shields 76, 77 and 78, of annular configuration, are used for the purpose of preventing corona discharge. Other configurations for the terminal and supporting assembly may be used without departing from the spirit and scope of this invention, the requirement for such an assembly being that it provide the necessary physical support for the fusor anode and cathode elements and also be capable of supplying the anode and cathode elements with the operating voltages without producing corona discharges or field emission.

All of the ion guns 22 and 22*a* are identically constructed such that a description of one will suffice for all. For this purpose, reference is made to FIGS. 11, 13, 19, 20 and 21. Each ion gun includes a conductive housing or sleeve 79 of stainless steel or the like which is perimetrically sealed to an opening 80 in the anode shell 20. The sleeve 79 is positioned such that its axis coincides with a diameter of the anode 20. Coaxially secured internally to the sleeve 79 and against the anode 20 is an aperture plate 81 having a beam-defining aperture 82. Coaxially positioned inside the sleeve 79 in radially spaced and insulated relation therewith is an anode sleeve 83 having a frusto-conically shaped bore 84, the smaller diameter end of this bore being positioned as shown. Three arcuately shaped and circumferentially spaced insulators 85 surround the anode 83 in spaced relation therewith. For securing these insulators 85 to the anode 83, a thin metal ribbon 86 fits into a shallow circumferentially groove and binds the three insulators 85 against the anode 83.

Axial positional support for the anode 83 is provided by means of three ceramic, axially extending posts 87 which are fastened to the outer surface of the anode 83 at points spaced circumferentially equally part. One such post 87 is shown in FIG. 13. Considering this latter figure along with FIGS. 20 and 21, these three posts 87 are secured to a metallic mounting ring 88 which in turn is secured at its outer periphery to a cap assembly indicated by the numeral 89. This cap assembly 89 is composed of suitably machined metal parts formed to a substantially cylindrical shape of somewhat larger diameter than the sleeve 79, this cap assembly 89 being hermetically sealed to the sleeve 79.

As shown more clearly in FIGS. 19 and 21, three power supply terminals 90, 91 and 92 are mounted in the cap assembly 89 and are spaced circumferentially apart 120°. The terminal 90 has a wire conductor 93 internally thereof which passes coaxially through one of the supporting posts 87 and connects to the anode 83. The terminals 91 and 92 have suitably strong, bar-like conductors 94 and 95 which project into the central portion of the gun and pass through a block 96 of insulation for maintaining the spacing therebetween. At the innermost ends of these conductors 94 and 95 is connected a thermionic filament 97, this filament being in the form of a circular loop of wire located coaxially with respect to the axis of the ion gun. As shown in FIG. 11, this filament 97 is situated to the rear of the anode 83.

A pipe fitting 98 is also secured to the cap assembly 89 midway between the two filament terminals 91 and 92 and communicates with the inside of the ion gun as shown. By means of this pipe connection 98, fusion-reactive gas may be admitted to the interior of the ion guns from a suitable source 45 (FIG. 9) by the adjustment of series-connected hand valves 99.

The anode 83 is maintained insulated from the surrounding sleeve 79 such that a power supply 100 may be connected between this anode 83 and the sleeve 79 as well as the anode 20. In FIGS. 11 and 13, such a power supply 100 is indicated as being connected with the positive electrode to the terminal 90 and the negative electrode to ground and the housing 79 of the ion gun. This power supply 100 in an operating embodiment of this invention is designed to supply a voltage which is variable between the limits of 0 and 1,000. A suitable voltage connected between the two terminals 91 and 92 (FIG. 21) serves to energize the filament 97.

Each ion gun 22 in operation generates and emits a beam of ions which is directed toward the fusor center 26. In order to approach this center 26, the beam must penetrate the cathode structure 36, 21, and for this purpose a suitable aperture assembly is provided therein. This assembly is indicated in enlarged detail in FIGS. 16 and 17 and is shown in proper coaxial relationship with respect to the ion guns in FIG. 11. Each aperture assembly includes an annular insert 101 having smoothly radiused corners, which tightly conductively fits into a companion aperture 102 in the shell 36. The shell 21 is provided with an aperture 103 of the same diameter as aperture 102 in precise radial registry therewith.

The beam emitted from the respective ion gun 22 passes through the annulus 101 and the aperture 103. Each aperture 38 in the cathode shell 36 is covered with a biasing screen indicated by the numeral 104 (FIGS. 14 and

15), this biasing screen 104 being secured in position by means of a first mounting ring 107 secured to the outside of the shell 36 in registry with the opening 38 and another ring 106 which clamps the screen 104 to the ring 105. The aperture 37 in the shell 21 is of a size equal to that of the aperture 38. The two rings 105 and 106 are firmly, conductively secured to the shell 36 by means of a series of circumferentially spaced screws 107.

Except where otherwise stated, the structure of FIG. 11 is fabricated of metal and primarily of stainless steel. The cathode shell 21 should be of a material which is photoelectric, and two suitable materials having the necessary properties are stainless steel and molybdenum. Other material obviously may be used without departing from the spirit and scope of this invention.

Inasmuch as the dimensions of the structure of FIG. 11 are relatively small in comparison with the operating voltages which are used, it is of course necessary to take the usual precautions in connection with preventing field emission and corona discharge. Suitable corona shields in various places are used as explained in some detail hereinabove, and all sharp edges, corners, points and the like, from which field emission could occur, are avoided.

The ion guns 22 and 22*a* are disposed in pairs which are diametrically opposite each other. Additionally, the axes of these opposite pairs are set to be coincident such that the ion beams emitted thereby will occupy essentially the same pencil-like space. This space passes through the fusor center 26.

The operation of the device of FIG. 11 is essentially as has already been described hereinbefore in connection with FIG. 9. To start with, all operating voltages are turned "Off" and a suitable vacuum pump 44 is connected to the interior of the anode shell 20. Referring to FIG. 11, such a vacuum pump is connected to an outlet port 108 in the cap 109 which seals the end of pipe section 52. Thus, gas inside the anode 20 as well as the cathode shells 21 and 36 may be evacuated therefrom, through the pipe sections 50 and 52, through webs in the disc 57 and out of the port 108.

The pump 44 is allowed to operate for a sufficient period of time and the fusor is otherwise outgassed so as to remove contaminates which could interfere with operation.

After outgassing and evacuating the fusor to a pressure of from 10^{-9} to 10^{-10} millimeters of mercury, a suitable fusion-reactive gas, such as deuterium, from gas sources 45 and 45*a* (FIGS. 9 and 11), is admitted to the ion guns 22 and 22*a* by adjustment of the valves 99. For this purpose, these valves 99 are opened just sufficiently to admit small quantities of gas which will raise the pressure to from 10^{-6} to 10^{-4} millimeters of mercury. However, just prior to admitting this gas to the ion guns, operating voltages are applied to the fusor as previously explained. In this connection, in order to have complete control of the fusor operation, it is desirable that all voltages be applied progressively starting from zero voltage. Initially, the voltage is applied to the terminals 91 and 92 for heating the filaments 97 of all of the ion guns 22 and 22*a*. Next, the voltages of ion gun power supplies 100 are increased progressively starting with zero voltage until a sufficiently high difference of potential is applied between the anodes 83 and the respective filaments 97 so as to ionize the fusion reactive gas that has been admitted and to form ion beams. Next, the power supply 25 is steadily increased in voltage until fusion reactions are noted. The detection of neutron counts by usual methods can serve as such an indication. The power supplies 100 are adjusted until a satisfactory degree of ionization as well as suitable intense and compact ion beams are obtained which are directed toward the fusor center 26. Instrumental in the formation and acceleration of these ion beams is, of course, the potential applied to the anode 20 and the cathode 21, 36.

The vacuum pump 44 connected to the port 108 may be kept operating continuously so as to maintain the neutral gas pressure within the fusor to suitably low levels, and, additionally, the gas valves 99 may be opened slightly or may be opened and closed intermittently for the purpose of supplying necessary quantities of fuel gas to the fusor in order to obtain the reactions desired. By adjusting the high voltage supply 25, the reaction rate can be changed. Similarly, adjustment of the ion gun anode voltage can affect the reaction rate. Increasing and reducing, selectively, the quantity of neutral gas admitted to the fusor also affects the reaction rate. Therefore, desired reaction rates may be controlled by adjustment of the various circuit and system parameters. A gas pressure of about 10^{-5} mm. Hg continuously maintained has been found suitable for producing fusion reactions.

As shown in FIG. 12, the switch 47 which is connected in series with the high voltage supply 25 is closed, and the neutron-producing reactions just described are obtained. If it is desired to obtain an electrical output from the fusor, it is only necessary to open the switch 47 to place the resistor 46 in series with the high voltage supply. As the reaction rate increases within the fusor and reaches a suitably high value, a reverse current is developed in the circuit of the anode 20 in the direction of the arrow Z adjacent to the resistor 46. This results in the development of a voltaged drop across the resistor 46. This reverse current Z will develop when the voltage generated on the anode 20 exceeds that of the supply 25. Once this self-sustaining operation is achieved by the generation of this anode voltage, the high voltage supply 25 may be taken out of the circuit by first disconnecting the battery and then providing a conductive or essentially short circuit in place of the supply 25. However, such a circuit change is not necessary if the supply 25 is adapted to conduct current in the reverse direction.

In order to form the poissor in the center of the cathode 21, 36, it is, as previously explained, necessary to have both ions and electrons. These ions are supplied primarily by the ion guns 22 and 22*a*. The electrons are in part provided by photoemission from the internal surface of the cathode shell 21. The ions from the ion guns 22 and 22*a* establish the initial virtual anode as previously explained in the central volume of the cathode shell 21. The poissor thereupon forms, as previously explained. Electron flow from the inside of the cathode shell 21 to the anode 20 is inhibited by reason of the fact that the cathode shell 36 is biased negatively with respect to the shell 21. This bias is supplied by the power supply 43 and is adjusted to a value at which the external anode 20 current is reduced to a desired minimum. The screens 104 over the openings 38 in the outer cathode shell 36 provide the desired equal potential surface which is more negative than the potential on the cathode shell 21. This inhibits the escape of electrons from the inside of the shell 21, thereby reducing losses due to the interception of such electrons by the anode 20. Also, the screens 104 prevent the positive field from the anode 20 from entering the apertures 37 of the cathode shell 21 and upsetting the spherical configuration of the equal potential surface therein, as previously explained.

The various aperture pairs 37 and 38 are arranged in diametric opposition for radial ion traversal. A cathode shell 21 and 36 construction of about 70% openness provides adequate ion permeability.

Alternative working embodiment

In FIGS. 22 through 26 is illustrated an alternative working embodiment wherein like numerals indicate like parts. Basically, the difference between this embodiment and the one just described and shown in FIG. 11 resides in the use of a single cathode shell assembly 21 instead of the double-shell arrangement 21 and 36 of FIG. 11. The construction of the fusor of FIG. 23 to the extent that it differs from the arrangement of FIG. 11 will be described in detail in the following.

The cathode shell **21** of FIG. 23 is mounted in concentric relation with respect to the anode **20** by means of the pedestal assembly **49***a* which corresponds to the assembly 49 of the fusor of FIG. 11. This assembly **49***a* includes a stainless steel or the like supporting tube **50***a* secured at one end to the anode **20** as shown. An apertured disc **110** is perimetrically fastened inside the tube **50***a* in the position shown and has secured thereto a ceramic post **111** which projects coaxially through the tube **50***a* to a position just inside the anode **20**. The opposite end of the ceramic post **111** is secured to a mounting plate **112** suitably rigidly secured to the cathode shell **21**. All the parts just described are sufficiently strong and rigid to position securely the cathode **21** with respect to the anode **20**.

The left-hand end of the tube **50***a* of FIG. 23 is adapted to have a vacuum pump connected thereto the same as has already been described in connection with the preceding embodiments.

The high voltage terminal assembly **72***a* corresponds to the assembly 72 of FIG. 11. This assembly **72***a* comprises a conductive tubular assembly **71***a* capped at its right-hand end as shown in FIG. 23 with a bottle-like insulator **113** which is sealed in vacuum-tight relation to the tubular assembly **71***a*. Extending coaxially through the assembly **71***a* and the insulator **113** is a rod-like electrode **114** which corresponds to the tubular element **68** of FIGS. 11 and 12. The inner end **68***a* of this electrode **114** has rigid conductors **115** connected to a mounting plate **116** secured to the cathode **21** as shown. The opposite end **117** of the electrode **114** penetrates in vacuum-sealed relation the re-entrant end wall portion **118** of the insulator **113** to have connected thereto the high voltage leads shown diagrammatically in FIG. 23. The parts **71***a*, **113**, **114**, **115** and **116** are sufficiently strong and rigid as to assist in centering and securing the cathode **21** within the anode **20**. A suitable bellows structure **119** is incorporated within the assembly **71***a* along with a threaded micrometer adjustment **120** for tilting the assembly **71***a*, **113** slightly so as to position adjustably the cathode **21** within the anode **20**. The total support for the cathode is provided by the two assemblies **49***a* and **71***a*.

The cathode **21** itself may be made identical to the cathode **21** of FIG. 11, apertures **37** and **103** being provided therein. The biasing function of the outer shell **36** of FIG. 11, however, is performed by a biasing screen assembly shown in enlarged detail in FIG. 24 and identified generally by numeral **121**. This assembly includes an annular spacer **122** of stainless steel or the like which has secured to the underside thereof a fine mesh, conductive screen **123** which full covers the aperture **37**. Concentrically positioned on the peripheral portion of the screen **123** is an annular insulator **124** L-shaped in cross-section as shown. Seated on the insulator **124** is another spacer **125** of some suitable conductor such as stainless steel which has secured to the upper side thereof a second screen **126** like the other screen **123**. The screen **126** is arranged parallel to but is spaced from the screen **123** for performing the purposes previously explained in connection with the screens of FIGS. 14 and 15 which are attached to the outer cathode shell **36**.

Fitted over the spacer **125** is another annular insulator **127** of L-shaped cross-section which engages the main spacer **122** for holding the second spacer **125** in concentric position.

Superposed on and in engagement with the spacer **122** and the insulator **127** is a flat annular retaining ring **128** which clamps the parts **124**, **125** and **127** into assembly. An annular cap **129** fits over the retaining ring **128** as shown, and a plurality of circumferentially spaced screws **130** passing through the parts **129**, **128**, **122** clamp the latter together and secure the same to the cathode **21**.

A sleeve **131** of insulating material is radially secured within a companion aperture in the main spacer **122** as shown and receives therethrough a conductive connecting wire or lead **132**. This lead at its inner end is conductively connected to the spacer **125** by being clamped between the spacer **125** and the insulator **124** as shown. Each of the apertures **37** in the cathode **21** is provided with a biasing screen assembly **121** as just described and the leads **132** of all of these assemblies are connected together so that the biasing potentials applied to all of the screens **126** will be the same.

As in the fusor of FIG. 11, each of the cathode apertures **103** of the fusor of FIG. 23 is coaxially aligned with the beam axis of the respective ion guns **22** and **22***a*. However, in each of the apertures **103** of the fusor of FIG. 23 is provided a biasing-electrode assembly shown in enlarged detail in FIG. 25. This assembly includes a tubular sleeve **133** of ceramic having an enlarged annular projection **134** thereon. The sleeve **133** intimately fits into the cathode opening **103** with the projection **134** seating against the outer cathode surface. A tubular metal insert or electrode **135** is snugly received by the sleeve **133** as shown and is provided with an end portion **136** which engages the bottom end of the sleeve **133** as shown. The upper end of the insert **135** is flared outwardly into a smoothly radiused flange **137** which overlaps the upper end of the sleeve **133**. A suitable wire-like conductor **138** is wrapped around the insert **135** between the flange **137** and the upper end of the sleeve **133**. This wire **138** is of such diameter as to have a wedging fit between the flange **137** and the sleeve **133** thereby locking the electrode **135** to the sleeve **133**. The assembly described thus far is finally secured to the cathode shell **21** by means of a clamping ring **139** fitted over the projection **134** and welded to the shell **21**.

Either as a part of the wire **138** or otherwise secured thereto is a connecting lead **140** for applying a biasing potential to the electrode **135**. As will now be apparent, this electrode **135** is insulated from the cathode **21**.

All of the ion-aperture assemblies as shown in FIG. 25 are interconnected by leads **140**. All of these leads **140** are interconnected with the leads **132** of the biasing screen assemblies **121** so that the electrodes **135** will have the same biasing potential applied thereto as the various screen **126**.

Biasing potential is connected to the biasing electrodes **135** (FIGS. 24 and 25) by means of the assembly shown in FIG. 26. This assembly includes an evacuated tubular housing, indicated generally by the numeral **141**, composed of tubular housing **142** of metal hermetically sealed at the inner end to anode **20** and at the outer end to a glass insulator **143** also of tubular configuration. Coaxially within the tubular housing **141** is a center conductor assembly composed of a metal tube **144** which is hermetically sealed at its outer end with a metallic plug **145**. A tubular conductor **146** is also sealed at one end to the plug **145** and receives on the other end a sleeve-like terminal **147** hermetically sealed at **148** to the conductor **146** and at the end **149** to the outer end of the insulator **143**. The space between the outer wall **142**, **143** and the conductor assembly **144**, **145**, **146** is vacuum-tight and in communication with the fusor interior. A metal cap **150** conductively carrying a sleeve-like contactor **151** telescopes over and conductively engages the terminal **147**. The cap **150** is molded into a protective rubber cover **152** which carries a conductive pin **153** connected at one end to the cap **150** and projects outwardly to a point at which a connection may be made to an external biasing circuit. This biasing circuit is indicated as being in the form of a battery **154** having its positive terminal connected to the cathode shell **21** and the negative terminal to the pin **153**.

A loop of spring wire indicated by the numeral **155** conductively engages the peripheral portions of one of the screens **126** and is formed by convoluting one end portion of a wire **156** which extends through the conductive tube **144**. This wire **156** is of such length that the upper end thereof engages the conductive plug **145** and makes conductive contact therewith. The wire **156** is maintained in position within the tube **144** by means of a small metal ring **157** fitted into the end of the tube **144**. It will now be seen that by providing one of these assemblies **141** on the fusor of FIG. 23, biasing potential may be applied to all of the screens **126** and ion-aperture electrodes **135**.

Referring to the ion guns **22** and **22***a* of the fusor of FIG. 23, it should be noted that annular magnets **158** are provided thereon which encircle the sleeve elements **79**. These magnets **158** have one pole adjacent to the anode **20** and the other pole outwardly therefrom. They are positioned with respect to the anode **83** (FIG. 13) such as to lengthen the travel of the electrons emitted by the cathode **97** axially of the gun thereby increasing the probability of ionization by each electron. This provides an increase in ion generation over the electrostatic arrangement shown in FIG. 13. In all other respects, the ion guns **22** and **22***a* of FIG. 23 are like that shown and described in connection with FIG. 13.

The operation of a fusor of FIG. 23 is the same as that of the fusor of FIG. 11 in almost all respects. The same techniques and operating voltages are applied, and all of the voltages are made variable so as to provide convenient control of fusor operation. As in the case of the fusor of FIG. 11, the bias on the screens **126** and the electrodes **135** and supplied by the battery **154**, for example, is adjusted to a value at which the external anode circuit current is reduced to a desired minimum. The screens **126** over the openings **37** in the cathode shell **21** provide the desired equipotential surface which is more negative than the potential on the cathode shell **21** as well as the inner screens **123**. This inhibits the escape of electrons from the inside of the shell **21** thereby reducing losses due to the interception of such electrons by the anode **20**. Also, the screens **126** prevent the positive field from the anode **20** from entering the apertures **37** and disturbing the spherical configuration of the poissor therein, as explained previously.

The electrodes **135** form the same biasing function, these being more negative than the cathode shell **21**, thereby setting up equipotential surfaces which inhibit the outward flow of electrons from the interior of the cathode shell **21**.

Alternative ion gun

In FIGS. 27 through 29 is illustrated an alternative ion gun **22***b* which may be substituted for the guns **22** and **22***a* of the preceding embodiments. Comparing this gun **22***b* with the one of FIG. 13, like numerals will indicate like parts. Instead of providing a cap such as **89** in FIG. 13 for sealing off the end of the gun, a ring flange **89***a*, like the flange **87**, is used for mounting one end of a tubular anode extension, indicated by the numeral **159**. The outer end of this extension **159** is hermetically sealed by means of a cap structure **160**. Thus, it will be noted that the body or envelope of the gun **22***b* which includes the parts **79** and **159** is considerably longer than the bodies of the guns **22** and **22***a*.

Carried by the wire conductor **93** of the terminal **90** is a tubular electrode **161** which corresponds to some extent to a control grid in an ordinary vacuum tube. This sleeve **161** is secured to the conductor **93** and additionally has a conductive connection **162** to one of the filament leads **94**. The filament **97** as well as the electrode **161** are biased negatively by means of a battery **163**, the negative terminal being connected to the conductor **93** and the positive terminal to the body of the gun **22***b*. This body **79**, **159** constitutes a conductive extension of the anode **20** such that it is operated at the same potential as the anode **20**. Surrounding the anode extension **159** is a series of bar magnets **164** arranged with the longitudinal axis thereof parallel to the axis **165** of the gun **22***b*. Supporting these bar magnets **164** are two axially spaced mounting rings **166** and **167**, these rings being made of iron or some equally suitable, highly magnetic material. A band **167***a* clamps these magnets onto rings **166** and **167** and retains them in assembly. There are six such magnets used in the arrangement of FIG. 27 as shown more clearly in FIG. 28; however, either a greater or fewer number may be used without departing from the scope of this invention.

In operating the guns **22***b*, the same conditions of fusor operation as explained previously are observed. More specifically, with respect to the gun **22***b*, a suitable filament voltage is applied to the filament **97** for the generation of ionizing electrons. Since the filament **97** is substantially contained within the length of the electrode **161**, the electrons in order to travel to the anode **159** must move axially of the gun. By reason of the focusing influence of the magnets **164**, the electrons will be directed rightwardly as viewed in FIG. 27 in a spiral path until they are eventually collected by the right-hand end portion of the anode **159**. Fusion-reactive gas admitted to the gun via the fitting **98** will be ionized by these electrons, such ions thereupon coming under the influence of the more negative electrode **161** as well as the fusor cathode **21**. The ions eventually are accelerated through the aperture **82** and form into beams which travel paths intersecting the tube center **26**.

Higher ion currents may be obtained from the ion guns **22***b* than those of FIG. 11 inasmuch as the ionizing electrons emitted from the filament **97** (FIG. 27) are accelerated through longer paths before interception by the anode; hence, they have a greater probability of producing ions before being intercepted.

In the following are given dimensions and values for system and circuit parameters for the embodiment of this invention as shown in FIG. 23, these being given by way of illustration only and not by way of limitation.

Dimensions

Internal diameter of anode shell **20**	inches	6
Thickness of anode shell **20**	do	0.093
Anode **20** material		[1] 304
Internal diameter of cathode shell **21**	inches	4.38
Thickness of shell **21**	do	0.060
Cathode **21** material		[1] 304
Size of openings **37**	inches diameter	1.75
Size of openings **103**	do	0.625
Inner diameter of rings **124**, **125**, **127**	inches	1.500
Size of screens **123** and **126**	mesh	[2] 15
Spacing between screens **123** and **126**	inch	0.140
Overall height of assembly **121** radially beyond cathode **21**	inch	0.320
Inner diameter of electrode **135**	do	0.437
Length of electrode **135**	do	0.500
Distance electrode **135** projects radially outwardly from cathode **21**	inch	0.312
Size of opening **80**	do	1.125
Outer diameter of sleeve **79**	do	1.500
Inner diameter of aperture **82**	do	0.500
Internal axial length of gun **22**, **22***a*	do	2.875
Length of anode **84**	do	1.000
Minimum inner diameter of anode **84**	do	0.625
Maximum inner diameter of anode **84**	do	0.825
Spacing of filament **97** from the adjacent end of anode **84**	inch	0.125
Space between anode **84** and sleeve **79**	do	0.187
Thickness of aperture ring **81**	do	0.375
Distance between ring **81** and anode **84**	do	0.500

[1] Stainless steel.
[2] Woven tungsten.

For a neutron count of 10^9, the following operating parameters for the fusor of FIG. 23 may be used as an approximation. Adjustments of voltages and dimensions may be required for obtaining this precise count.

Fusion-reactive gas	Deuterium and tritium, equal portions.
Neutral gas pressure in fusor	2 microns.
Anode **20** circuit current	30 milliamperes.
Anode **20** applied voltage	100 kilvolts.
Voltage of supply **100** as applied to the anode **84**	250 volts.
Voltage applied to the filament **97**	6 volts.
Filament **97** current	7 amperes.
Bias voltage on screens **126**	500 volts.

A viewing port assembly **168** is attached to the anode **20** as shown in FIG. 27 for the purpose of permitting observation, either directly or indirectly by means of closed circuit television equipment, of the reaction which occurs in the center, the outer end of the assembly **168** being vacuum sealed by reason of a window **169**.

While there have been described above the principles of this invention in connection with specific apparatus, it is to be clearly understood that this description is made only by way of example and not as a limitation to the scope of the invention.

What is claimed is:

1. In a device for producing nuclear reactions, anode means, cathode means inside said anode means, said cathode means defining a volume centrally located with respect to both said anode and cathode means, said volume being free of tangible structure, said cathode means being open to the flow of gaseous particles therethrough, a fusion-reactive gas within said volume, means supplying a potential between said cathode and anode means for establishing an electric field therebetween, means including said cathode and anode means and said potential-supplying means for accelerating ions of said gas to fusion-reacting energies along converging radial paths in said volume, and means for inhibiting flow of electrons from said volume to said anode means, said inhibiting means including means for biasing the open portions of cathode means more negatively than the cathode means itself.

2. The device of claim **1** wherein said volume is substantially spherical in shape and said paths have a common intersection in the central portion of said volume, and further including means maintaining said gas at sub-atmospheric pressure.

3. The device of claim **1**, said cathode means being a generally spherically shaped metallic shell having a plurality of openings therein.

4. The device of claim **3** wherein said anode means is a generally spherically shaped metallic shell concentrically surrounding said cathode shell, said inhibiting means including a plurality of biasing electrodes, one electrode for each opening, said biasing electrodes having portions peripherally coextensive with said openings, respectively, and means for applying biasing potential to said biasing electrodes for establishing said equipotential surfaces.

5. The device of claim **4**, including means connected to said anode shell for generating and injecting charge-particles into the space between said cathode and anode means, the magnitude of said electric field being adequate to direct at least a portion of said charge-particles through at least a portion of said openings and into said volume.

6. The device of claim **4**, including a plurality of ion guns carried by said anode shell in radial alignment with respective ones of said openings, means including said ion guns for directing ions through said openings and into said volume, whereby ions from said guns may be projected toward the opposite side of said anode shell.

7. The device of claim **6** wherein the first openings diametrically aligned with said ion guns, respectively, are free of structure and the remaining second openings are covered with biasing screens, respectively, means insulating said screens from the cathode shell next adjacent to said volume, the biasing electrodes for said first openings including annular elements coaxially fitted into the respective cathode shell openings, said annular elements being insulated from said cathode shell.

8. The device of claim **7** wherein each of said second openings is covered with two screens, the first of said screens being conductively mounted on said cathode shell, each second opening further having an annular insulating device coaxially surrounding the same and operatively mounted on the outer side of said cathode shell, each insulating device having a second of said screens mounted thereon spaced from the first screen, and connections to said second screens for biasing the same negatively with respect to said cathode shell.

9. The device of claim **6**, wherein the means for maintaining said gas at sub-atmospheric pressure includes a supply of neutral fusion-reactive gas connected to said ion guns and also means for controlling the pressure of said gas as admitted to said ion guns in the range of from 10^{-3} to 10^{-8} millimeters of mercury, said ion guns and said anode shell being hermetically sealed and in communication with each other, said controlling means including a vacuum pump for exhausting gas from within the space of said anode shell.

10. The device of claim **2**, said anode means incudling a generally spherical anode shell, said cathode means including two generally spherical concentric cathode shells spaced apart a predetermined distance, said two cathode shells having a plurality of openings therein which are in radial registry, said cathode shells being concentric with respect to said anode shell, means for biasing the outer one of said cathode shells more negative than the inner one.

11. The device of claim **10**, including means connected to said anode shell for generating and injecting charge-particles into the space between said cathode and anode shells, the magnitude of said electric field being adequate to direct at least a portion of said charge-particles through at least a portion of said openings and into said volume.

12. The device of claim **11**, including a plurality of ion guns carried by said anode shell in radial alignment with respective ones of said openings, means including said ion guns for directing ions through said openings and into said volume, whereby ions from said guns may be projected toward the opposite side of said anode shell.

13. The device of claim **12**, wherein the first openings diametrically are free of structure and the remaining second openings of the outer cathode shell are covered with biasing screens, respectively, said screens being conductively secured to said outer cathode shell, said means for maintaining said gas at sub-atmospheric pressure includes a supply of neutral fusion-reactive gas connected to said ion guns and also means for controlling the pressure of said gas admitted to said guns in the range of from 10^{-3} to 10^{-8} millimeters of mercury, said ion guns and said anode shell being hermetically sealed and in communication with each other, said controlling means including a vacuum pump for exhausting gas from within the space of said anode shell.

14. The device of claim **13** including means connected to said anode means for coupling electrical power therefrom.

15. In a device for producing nuclear reactions comprising anode means, cathode means inside said anode means, said cathode means defining a volume free of tangible structure, a fusion-reactive gas within said volume, said cathode means having openings for the traversal therethrough of charge-particles, means including said anode and cathode means and ions of said gas forming a space charge in the central portion of said volume, said space charge including electrons and ions of said gas so distributed as to produce a substantially spherical electric field which confines target ions in a point-like region in said central portion and oscillates projectile ions through said region at nuclear reacting energies, whereby fusion reactions result from collisions between said projectile ions and between said projectile ions and target ions, and means for biasing the openings in said cathode means negatively with respect to said cathode means for inhibiting the flow of electrons from the volume inside said cathode means to said anode means.

16. The device of claim **15** wherein said space charge is arranged in a configuration which provides a spherical virtual anode concentrically surrounding a spherical virtual cathode, said cathode means including a generally spherical shell concentrically surrounding said virtual anode thereby providing an electric field therebetween which exerts a force outwardly on a positively charged particle in a direction radially toward said cathode means, the potential of said virtual anode being of a magnitude which propels ions inwardly and oscillates them as projectiles through said virtual cathode at nuclear-reacting energies, whereby collisions of ions in the region of said virtual cathode produces nuclear reactions.

17. The device of claim **15** wherein said gas is of a composition that reactant products of fusion include positively charged particles which are propelled outwardly against the field of said anode means with sufficient energy to transfer the charges thereof to said anode means thereby generating electrical power, and circuit means connected to said anode means for coupling the generated electrical power therefrom to a utilization device.

18. The device of claim **17** wherein said anode means includes a generally spherical conductive anode shell, said cathode means includes a generally spherical conductive cathode shell concentrically positioned inside said anode shell, said cathode shell having said openings therein, said positively charged particles passing through said openings in transit from said volume toward said anode shell, and said circuit means including a load impedance connected in series between said anode and cathode means whereby said generated electrical power may be coupled from said impedance to a utilization device.

19. The device of claim **17** wherein said space charge-forming means includes a power supply connected to said anode and cathode means for applying an operating voltage thereto; the value of said operating voltage, the composition of said gas and the number of gaseous particles within said volume being so related that the fusion reactions are self-sustaining and contribute more power to said circuit means than is consumed in initiating such reactions.

Bio Cybernetics Revisited
by
G. Harry Stine

When Jerry Pournelli and I started to write these columns as a vis-a-vis experiment, we hoped that sooner or later one of us would write something that the other could tee off on and thus get a good controversy going that would present "alternate views." It hasent worked out that way because Jerry and I have discovered that we think very much alike on most matters. We have not been able to stir up controversy between one another. But we did stir up controversy among the readers.

When I wrote the columns on biocybernetics in the May and July 1979 issues, my objective was more or less than science reporting with some synthesis included. I wanted to point out that a true interface between human brains and electronic computers was not only possible but that the basic experiments have been done and the foundation technologies already existed, albeit in the case of the Flanagan neurophone the data had been generally unknown for 16 years. I reported on the basis of what I knew at that time. I requested that no one write for additional data because I didnt have any additional data at that time. I do now.

These two columns have resulted in an inordinate amount of mail from readers which makes the editor happy because he knows people are reading this. Some of the letters were anticipated, some were not. Some were from people who were deaf and wanted the Flanagan neurophone at any price. Others wanted the neurophone to use in attempts to contact loved family members in a coma. There were the usual letters from Ph.Ds who should know better than to make some of the statements they did. And I got letters with real up to date information...

You may obtain copies of his two neurophone patents by writing to the U.S. Patent Office and ordering Patent No. 3,393,279 granted July 16, 1968 and Patent No. 3,647,970 granted March 7, 1972.

The rights to Patent No. 3,393,279 are owned by Intelectron, Inc. of New York City. The FDA will not permit it to be marketed because it uses a low frequency r-f carrier, and they are very sensitive these days about the biological effects of r-f raditation.

But Pat Flanagan is an inventor. With his original patent rights in the hands of another company and with an FDA ban on its production, Flanagan developed the second neurophone device covered by Patent No. 3,647,970 which does not use an r-f carrier and does not involve high voltages. At the behest of the Department of Defense, the Department of Commerce placed Flanagan's new device under secrecy order No. 756,124 dated August 28, 1968. Flanagan was able to get this secrecy order rescinded in 1972 to permit the patent to be issued.

I sat in Flanagan's study and listened to the new neurophone on July 26, 1979. It works even better than the original one. It operates from eight Type AA alkaline penlight cells. The audio signal is double differentiated and converted to a 60 volt square wave which is then run through a zero crossing detector. The sensor electrodes are one inch diameter plates made from lead zirconium titanate insulated on one side with epoxy that also seals the attachment of the lead from the neurophone.

With one electrode placed on the soft skin of my calf and the other on my chest, I heard the audio information from the tape recorder input in my head. I listened to both speech and music, and the fidelity was outstanding. I had a cassette tape recorder running two feet from me while this was going on; there is no evidence of the audio information recorded on the cassette by the recorder; I was the only entity hearing the neurophone, and it was therefore not producing and sound waves that the microphone of the recorder could pick up.

As I knew 17 years ago, the Flanagan neurophone works. I dont give a doodly damn what all you bloody experts out there have presumptuously stated in your outraged fan letters to me. I am forced to repeat the immortal words of Dr. J. C. Warren voiced after performing the first surgery with a patient under ether anesthetic administrated by Dr. William Thomas Green Morton in Boston on October 16, 1846:

"Gentlemen, this is no humbug!"

For the benefit of all you who wrote me, I gave your letters to Flanagan. There is no need for me to be in the loop. There is no need for Flanagan to defend himself nor does he need help in doing so; he has a device that works. In the eyes of some sober, respected academicians, Flanagan is perhaps flamboyant and different, but that must not be allowed to detract from the fact that he is a successful inventor and, in common with many others of his unconventional and freewheeling nature in the history of science and technology, working on the fringes of scientific research in areas that others can't or won't touch.

The most fascinating aspect of this whole affair has been the confirmation and terrible realization that the human race apparently has not progressed beyond the state of affairs a century ago when "legitimate" scientist dug in to defend their sacred turf....and made damned fools of themselves in the process. They also retarded the development of technology that would have relieved human suffering and generally improved the human condition. These scientific brahmins still exist; they are no different from the predecessors of a hundred years ago; and they exhibit an appalling lack of knowledge and understanding of the history of their own field of expertise!

Arthur C. Clarke's law is still very much in force.

Jerry Pournelle was 100% correct in his June 1979 "The Alternate View."

I would like to extend my profound thanks and grateful appreciation to those scientific brahmnis who wrote to me and to the editor about the neurophone and the human computer interface. You have greatly contributed to the contents of my "Utter Bilge" file. This is my collection of presumptuous statements from people who should know better than to make such statements in the first place. The file title derived from in infamous statement of Sir Richard Van Der Riet Wolley: "Space travel is utter bilge!"

Scientific research and technical progress is not and has never has been the exclusive turf of any select group of people. There has always been a role for the amateur investigator, and still exists today. Before the "official" establishment of any new area of scientific endeavor, everyone who works in that area must, by definition, be an amateur. Even in the established fields of scientific endeavor, important discoveries have been made by amateur investigators. Good scientists and I have the pleasure of knowing many would never reject out of hand any amateur findings and will react with enthusiasm and interest to such findings. It is only poor scientists who are insecure that will react negatively. Would there were more good scientists!

Bioelectronics today is about the same situation as electricity about a century ago. The field is ripe for experimentation. Certainly there is danger; there always is. But that is no reason for suppressing information, as one PhD. correspondent demanded be done, for fear of someone electrocuting himself by building a neurophone in his basement shop. People still get hurt in steam boiler explosions. As a matter of fact, people still get burned handling the ancient technology of a campfire. These accidents merely strengthen the statement of Herbert George Wells, "History is a race between education and catastrophe," but down on the personal level.

To paraphrase Harold Laski, science by experts means, after a time, science in the interest of experts.....

Bio Cybernetics II

by
G. Harry Stine

Last time around, two issues ago, I reported on the process made by DARPA (Defense Advanced Research Projects Agency) concerning computer recognition of human EEG patterns. I stated that this was a major breakthrough in the development of the true intelligence amplifier wherein the human nervous system was linked directly with the electronic circuitry of a large general purpose computer. Soon, the crystalline circuitry of the computer will be able to "understand" the colloidal circuitry of the human nervous system by direct linkage through electromagnetic fields.

And I left you hanging by your fingernails on a figurative cliff overhanging an ammonia sea swarming with methane monsters, so to speak.

I stated that seventeen years ago the breakthrough had been made that would permit the colloidal circuitry of the nervous system to "understand" the crystalline circuitry of the electronic computer. In other words, if the computer signal was in the proper form, the human nervous system could pick up and decipher the electronic computer signal through an electromagnetic field.

In early 1962, I was working as assistant director of research for the Huyck Corporation in Milford, Connecticut. Dr. William O. Davis was the director of research, and he had been charged by the company to look for new products to insure that Huyck would be in business twenty five years hence. There were no caveats placed on us at that time. We could look at or for anything....and we did. Then as now I have all sorts of pipelines into the back rooms of various research and development organizations here and abroad; a science fact or science fiction writer really cant function properly without these contacts. My most valuable Little Black Spy was the former editor of this magazine. John W. Campbell, who in turn had an incredible network of Little Black Spies.

Campbell told me of an 18 year old boy in Texas who had invented a spectacular new hearing aid. I made a telephone call, talked to the boy, and was on a plane to Houston within days.

G. Patrick Flanagan of Ballaire Texas was a boy genius. In addition to being an outstanding gymnast and a pilot, this high school graduate had stumbled upon a technique of introducing audio information directly into the human nervous system without loudspeakers or earphones, and without direct electrical connection between his gadget and the nervous system.

On July 24, 1962 in Bellaire, Texas in Flanagan's shop in the attic of his parents home, I personally witnessed proof-of-principle demonstration of a direct linkage between a crystalline electronic circuit and the colloidal system of the human nervous system.

The device called the "neurophone" by Flanagan, was a very simple gadget. It used those ancient devices known as vacuum tubes. It used a 6L6G tube running as a 35 Kilohertz oscillator; the output of the oscillator was amplitude-modulated by the output of ant single channel hi-fi system through suitable impedance matching transformers, etc. This amplitude modulated 35 kilohertz signal then went through a cheapie stepup transformer so that the output was very high voltage (about 4 kilovolts, as I remember) but at very high impedance. Flanagan fed this signal through a length of ordinary TV antenna twin lead to a pair of rubber pads about six inches in diameter that he had filched from a "relaxicisor" muscle relaxing device. Each pad consisted of a 1/16 inch thick rubber sheet, a piece of copper window screen to which was soldered one of the wires of the twin lead, and the rubber covering of the relaxicisor pad. The rubber insulation kept one from getting zapped, although the shock wasnt painful....just annoying.

Put a signal into the neurophone input, peak the frequency, peak the modulation to 100%, and then hold the two pads to your body....anywhere.

And you heard music playing in your head!

Although the pads worked better and you got a louder signal with the pads on your bare skin, it would work through a layer of clothing.

And it worked regardless of where you put the two pads! You could put one on your shoulder and the other on the sole of your foot...and you would still hear whatever program material was being played into the neurophone form the hi-fi system.

I can freely describe this today because (a) I dont think Flanagan's patent application ever got accepted and I dont believe the patent ever issued. (b) Huyck Corporation is off doing its classic thing of making paper machine parts and isnt interested in the slightest, and (c) I think the time is just about right to get going on this little gadget again.

Flanagan had succeeded where others had failed. Dr Henry Puharich had succeeded in developing a similar device, but the pads were one inch copper plates that had to be rubbed along the skin to achieve the "fricative effect" to permit Puharich's gadget to work.

In a series of long and complex experiments conducted under my supervision at Huyck and by Dr Wayne Batteau at Tuffs, it was conclusively shown that the neurophone effect not the result of (a) the pads acting as electrostatic loudspeakers, (b) the pads exciting bone conduction of the sound, or (c) the pads activating the eighth cranial nerve. Although I tried the neurophone an a nerve deaf medical doctor at Columbia University in 1965, I kept the experiment running for only about ten minutes. Dr Wayne Batteau tried it at Tufts and succeed because the brain of his nerve deaf subject had "forgotten how to hear" and needed something over an hour of application of the neurophone signal in order to begin to hear in his brain again! We know now that the Flanagan neurophone operated by direct linkage of the electronic circuitry with the nervous system through electromagnetic fields. We know now that the nervous system will pick up any signal and send it to the brain where the brain recognizes the signal according to the sensory data it represents, then switches the signal to the proper sector of the brain responsible for processing such signals. But we dont know how Flanagan accidentally happened to crack the neural code for audio data.

I can assure you that the Flanagan neurophone is no hoax. Many responsible people experienced it. Just before his death, Dr William O. Davis gave me one of the neurophones we had built at Huyck; I still have it, but a two hour search through my uncatalogued archives of scientific memorabilia and trivia failed to locate it this morning. Im going to dig it out and try it again for fun. And because it does represent a breakthrough that will permit electronic computers to communicate directly to our nervous systems...by putting on a beanie, and not plugging a cable into a socket implanted on the top of our heads!

The DARPA work with computers deciphering human EEG signals, plus the Flanagan neurophone capable of permitting a computer to communicate directly with a human, both make inevitable the final computer; the use of the computer as a extension to the human brain as an intelligence amplifier for the human being.

Now, what happened with the Flanagan neurophone, and why havent you heard more about it? I am not sure that it is because of the reaction of Big Science as discussed by Jerry Pournelle last month. There were several factors involved.

First of all, it didnt look like Huyck could get a patent position, so they wanted out. They also discovered that the Huyck Corporate Research Laboratories were producing more inventions, patents, and potential new products than the company could possibly absorb. Huyck also got into production trouble with several products that have come along before Corporate Research entered the picture. So Huyck dropped the entire corporate research program, writing off about 2.5 million spent over a five year period. They also convinced themselves that they could not afford to develop the marketing know-how for any of the new products we were coming up with. They succumbed, as have so many other small companies, to the "Harvard Business School Syndrome": Dont develop new technology and products yourself, but wait until somebody else does and then buy the whole schmear, product, production, and marketing know-how in a big package. My employment agreement was written in a way that I wasnt sure what I could talk about....then.

Dr. Wayne Batteau suffered a fatal heart attack in Hawaii while diving with dolphins. He had also done considerable work in that area.

I dont know where Flanagan is. He worked for NASA in Houston for a time in computer programming. The last I knew, he was somewhere in California as one of the top experts pyramidology. I suspect I will hear from him as a result of this, and Ill welcome it.

Big Science did not kill the neurophone. It was complacent, and it really didnt know anything about the device. Academia was not really consulted. The neurophone has been dormant for fourteen years now because of the failure of nerve and imagination in the sales and marketing department.

But, now, there appears to be a need for the neurophone to take the final step toward direct communication between ourselves and our crystalline symbiotes/servants, the electronic computers.

Yes, I am still interested in this area. I am interested in anything and everything. But do not-repeat, repeat do not write to me or telephone me and ask for free information. I am a writer and a consultant, and my business is information...and the only thing of real value that you or I have in this world is time. I didnt write this soliciting business; I wrote it to report to you that the intelligence amplifier is just around the corner and awaiting you bright people out there to put it together right so that humans stay in control of intelligence amplifiers.

Now, what can we do in the future to integrate the creative process of "invention" more fully into the process of research, development, production, and marketing? Hang in there......

Meridian Balancing by Use of the Neurophone

Sheldon C. Deal, D.C., N.D.

Abstract ~

A series of experements were done by muscle testing paitents for meridian imbalences and then strengthing the muscle indicators, indicating balanced meridians, by running a time-domain amplifies signal through the patient's skin.

The skin is embryonically the source of all special senses. Our skin contains more sensors for heat, touch, pain, etc., than any other part of the human anatomy. The human ear evolves embryonically out of the convolutions of the skin of an embryo in the mothers uterus. Basically, the skin is the oldest evolutonary nervous system sensor. Another way to look at this, is the special sense of tough has progressively extended over the entire body by way of skin and evolutionary wise our other special senses should follow suit and extend over our entire body in time. The skin then, since it is the precursor of the ears, should also be capable of hearing, or to put it another way, it should beable to transmit the sense of hearing to the brain by means other than the 8th Crainial Nerve.

The skin is both piezo-electric and opto-electric, that is, when the skin is stimulated by an electric or photon field, it vibrates. If it is mechanically stimulated, it will generate its own electric and photon field. In Russia, blind people have been trained to "see" with their fingertips and in Czechoslavakia, deaf people have been trained to "hear" with their fingertips.

For the purpose of our experement, we used a Neurophone, a device developed by Dr Pat Flanagan, author of the book, *Pyramid Power*. The device uses hyperspacial nested modulation technology. Briefly the device takes a complex signal such as the sound of an orchestra and electriclly processes it. First, the signal is passed into a section which clips everything into a series of square waves, remarkably analogous to the sort of clipped waves Lisitsyn confirms are the carriers of the human brain waves. Next, the square waves are differentiated, since these are finite spikes with real non-zero rise times and decay times rather than theoretical constructs, a series of noisy spikes results the second differentiator section. From here, the noisy spikes are introduced to special contact electrodes which are placed on the skin. The electrodes are fabricated of zirconium titanate imbedded in acrylic plastic tiles to provide maximum impedance match to the skin itself.

In experements done at Tufts University near Boston by Dr Dwight Batteau in Man-Dolphin communications and assisted by Dr Flanagan, it was established that the nervous system uses time ratios as major sources of intelligent information. It was found that speech intelligibility was contained in time dominant ratios of the speech waveform. Speech quality was found to be contained in dominant frequency ratios. So the nervous system is designed to recognise two distinct paramaters: the time domain and the frequency domain.

Baised partially upon work done at Tufts University, it is known that the human voice does not depend upon frequencies. People who have had their larynix removed can use an "artificial larynix", a buzz generator held against the side of the throat. Word information is formed by the action of the jaw, tongue, teeth, glottis, and the nasal cavaties. The human nose and mouth form a variable time dely generator. Thus, the basic audio information our brains evolved to decipher, the human voice, is dependent not upon frequency but upon the time rate of change nature of sound caused by time delays imposed by the mouth and nasal passages.

The Neurophone makes use of these research results by suppressing the frequency domain and amplifying the time domain of the incomming signal. This is one reason why the Neurophone sounds so scratchy when one first begins to listen to it. The electronic circuitry of the Neurophone presents audio information to the skin in the way the skin originally evolved to recieve and decode the information eons ago. Thus the Neurphone directly inputs information into the brain and nervous system, and even the mind, bypassing all the normal sensory systems that lie between the mind/brain loop and the outside environment.

Since all of the acupuncture meridians are present on the surface of the skin, we found some very interesting affects when the skin was activated by the Neurophone. All the subjects of the experement were muscle tested fo r one major muscle for each of the twelve meridians bilaterally. The meridians were recorded as under active for muscle weak in the clear and over active for muscles that became weak only by stimulation of the alarm point for its respective meridian. The subjects were then connected to the Neurophone by placing the electrodes on the skin of the forehead just lateral ans superior to the eyes. K-Y Jelly was used to enhance the contact between the skin and the electrodes. A tape recording of pink noise was then played through the Neurophone for a period of two minutes and then the muscles were retested after removal of the electrodes.

Conclusion ~

Table 1 represents the totals of 10 different paitents who went thorugh the experiment. Out of the 240 meridiand tested, 85.8% of the unbalanced ones found, were corrected. The Neurophone appears to have a beneficial effect on the body. On subesquent visits, the meridians were remaining in balance two weeks later. Some of the many comments from the paitents included: cessations of seizures, inproved sleep, total relaxation, improved respiration, better concentration, and cessation of pain.

Additional Research ~

To be certain the Neurophone was not operating by bone conduction, a simple experement was done, known as the Batteau test in honor of the hearing research of the late Dr Dwight Batteau who developed the test during the Neurophone evaluation at Tufts University.

Two seperate channels of auditory information were used. One channel goes through a set of ordinary headphones, the other goes through the Neurophone. One specific frequency is played through the headphone channel. Another frequency slightly different is played through the Neurophone circuitry to the transducer disks. If the Neurophone was producing hearing by bone conduction, the two slightly different frequencies would "mix" in the bone structures of the inner ear, producing a discernible "beat frequency" which is the difference between the two frequencies. With the Neurophone, this "beat" is heard only at very high volume levels in both channels, levels at which the Neurophone is probably producing bone conduction by the strong vibration of the skin under each transducer disk. However, the beat frequency should theoreitcally be heard at all volume levels; it is not heard at normal neurophonic listining levels.

Looking Ahead ~

Although the present experement was a relatively simple one, the implications of future possibilities are tremendous. The following ideas may well serve as topics of future research papers and I invite all the members of the I.C.A.K. to pursue them, either on their own or in conjunction with me. Some of the possibilities for which ther is already some evidence are:

1. Increase in telepathic awareness.

2. A brain/mind link between two or more people. T.E. Bearden has developed a mathematical formula that indicates that the combined mind power of a group of people will multiply exponentially if these people are linked in a unitary consciousness.

3. Subliminal learning may be accomplished by the subject material being played through the Neurophone at a low volume level. No conscious effort is made to learn the material. This could even be accomlished while the student is asleep.

4. Conscious learning may be accomplished by simultaneously listening to tape recorded data by means of Neurophone and headphones. In this way, the learning centers of the brain are being accessed by at least two seperate channels.

5. Positive subliminal programs to alter undesirable habits: i.e., weight control, smoking control, and creation of positive mental attitude.

6. Control the aging process by means of positive cellular programming via the Neurophone.

7. Totally deaf people being able to the recorded audio.

Operation of the Neurophone on the Nervous System

by
G. Patrick Flanagan

Definitions: CRT = Critical Reaction Time

In a purely rate of onset pulse information system, the pulse rate of the system and the pulse amplitude of the system would remain the same. The things which will be varied, are the slope of the leading edge of the pulse, and inversely the width.

In this system, the amplitude,(e) of the pulse remains the same; so does the repeition rate of the signal. The only things to be changed are the slope and thus the width of the top of the pulse. From now on, the slope in degrees will be represented by (à), and the width at the top will be represented by (T). We can then formulate an empirical formula for the relationship of à to T. (T measured in usec). T = K/à as à = 45 degrees, T = 0 or T = max time, à = 0 degrees. K = conversion factor.

Therefore T also equals I (instantaneous audio information).

The width of the entering pulse with no information must be equal to the CRT of the nervous system at any given instance. Then the slope of the pulse and thus the width at the top are varied, so is the response of the system. A pulse of the same amplitude but of the wrong width for the CRT of the neuron will only partially load the neuron. The amount or amplitude of the loaded signal in the neuron will be proportional to the width of the pulse as it is varied.

Now, if a sine wave is loaded into the system, the frequency of the wave must be varied so that the width of the wave will coincide with the varying CRT of the loaded system, otherwise the sine wave will have no effect on the neuron, i.e., very little.

It has been shown by my experimentation with the effects of adrenergia and cholinergia on the nervous system, that as the body goes into the state of adrenergia, the frequency of the carrier must be increased to meet the smaller CRT of the nerves introduced by the addition of adrenaline and acetylcholine into the system. And, as the body goes into a state of colinergia, the opposite is true, the frequency must be lowered, due to the increased CRT. Otherwise no information can be transmitted into the system.

In adrenergia, the excited state, the K ion mobility is increased and the CRT is smaller....thus requiring a higher frequency. In the case of cholinergia, the opposite is true.

Lets now analyze a 30 KHZ sine wave as applied to the nervous system and see what the nervous system sees. The sine wave is clipped at e and the width of the top of the clipped wave is < 15 usec. Now, if the nervous system at this instant has a CRT of approx 15 usec perfect loading will occur.

Now, if the CRT of the nervous system at this moment should change to 20 usec, the carrier would have to be shifted to 25 KHz to obtain the same response. This increase in CRT would indicate that the person had gone into a state of colinergia. The new CRT of the neuron would now cause the neuron to be improperly loaded at 30 KHZ, but properly loaded at 25 KHz.

Now we will look and see what the effects of modulated and unmodulated carrier have on the system at the neurons CRT. According to the Encylopedia Britannica, the output frequency generated by a neuron is proportional to the amplitude of the stimulus, until the stimulus reaches a certain level and the frequency then remains the same is.. the clipping level of the system. The completely loaded neuron will then be receiving maximum stimulus and will then be generating a frequency of its own in proportion to the loaded voltage. At this loading in the unmodulated carrier, a series of meaningless pulses are being generated and sent to the brain where they are probably rejected and passed off as random noise.

Now let us look at a tone modulated carrier (AM Signal) and see what happens with some information input. The pulse width at the top (clipping) now varies with change in carrier amplitude at the audio tone modulation frequency. The loading voltage of the neuron will now vary with the audio rate....the varying width of the top of the pulse now follows a pattern of widths in time with the audio tone.

The overall process: (Audio) I = varies T and which vary e loading in neuron which generates freq to the brain. We now have a system that detects and interprets rate of change into the neuron's own coding system. Or, as applied to a purely rate of onset modulation system with a pulse input instead of a sine wave input. We now have a coded conversion system for introducing information into the nervous system.

The Neurophone Mark XI Manual
(1979)

G. Patrick Flanagan, Ph.D.

This year the neurophone concept has now reached maturity. It was developed 21 years ago this year (1979). The entire history of the neurophone reads like a James Bond mystery novel. We are currently writing a full length book on the neurophone story, and expect to publish this next year. For the present, we will give you a synopsis of the neurophone story, and bring the reader up to date on the current development of the neurophone Mk XI, the eleventh model in a long chain of discovery. following the basic history of the neurophone, we will give instructions for the set up and use of the neurophone.

The first neurophone was developed when I was 14 years old. A brief description of the original device is given in the book PYRAMID POWER. The original neurophone patent #3,393,279, describes a high voltage, high frequency, amplitude modulated radio oscillator. This device made the listener into a radio receiver. It transmitted sound information to the user by means of small insulated electrodes. The 3000 volt signal produced an electric field of extremely low power density. As the carrier frequency was in the vicinity of 50 Khz, and the capacitance of the electrodes was therefore extremely low. The above electrical conditions of low power density indicate that the original device was safe for use. However, if the electrode surfaces were scratched, the user would experience a mild, but annoying mild electric shock.

When I originally received the idea for the first neurophone, I was a child of 14, and did not have funds to hire a patent attorney. One of my fathers friends was a patent attorney for Shell Development Corporation, and agreed to help me write my own application. Over the years, I became very familiar with patent law, as the patent examiner in Washington said the neurophone could not possibly work, as it defied ALL present laws of neurophysiology. The patent fight over the neurophone went on for many years, finally resulting in complete rejection by the examiner, closing the file forever with no recourse.

In a brilliant move, my patent attorney (I could afford one by now) suggested that we go to Washington and demonstrate the neurophone to the examiner in a final attempt to gain approval. When we arrived at the patent office, the examiner had a real surprise waiting for us, he had arranged for a deaf employee of the patent office to be present for the demonstration! The deaf gentleman was nerve deaf in one ear, and almost totally deaf in the other ear. When the deaf employee heard high frequency sounds for the first time in 15 years, he wept for joy. The examiner then reopened the neurophone file, and issued the patent giving the original filing date.

By the time the patent was actually issued, a company in New York owned by Joseph Lawrence, and Andreja Puharich was infringing on my patent. It seems that they had applied for a similar patent several months after I had applied for mine. As I was the first to file, and had pursued the patent, I won the device. The small New York company bought the patent, and by means of legal maneuvers, succeeded in causing me to lose a small fortune in the process. This was due to their issuance of lettered stock which tumbled to a fraction of its original value by the time the SEC allowed me to sell it.

We have actually gone far ahead of our story, so we will backtrack a little. during the years in which I battled the patent office for the original patent many events took place. When I was 17 years old, LIFE magazine called and wanted to do an article on the device. When I was 14, I had received national publicity on the front pages of 300 newspapers. After the LIFE article came out, I was offered up to $8,000,000 for the patent rights. The press coverage was unbelievable. The Ive Got a Secret show(Gary Moore) invited me to New York, and millions of people saw the neurophone demonstrated on Bess Meyerson. It was during this show, when I first met Puharich and Lawrence.

Puharich invited me to lunch at the Twenty One club, along with G. Harry Stine, a scientist under the employ of a firm in Connecticut known as Huyck Corporation. Stine's company was interested in the rights to the neurophone.

When all the offers were in, my parents and my Houston attorney agreed that the neurophone should be given to Huyck. After examining the device for two years, Huyck said the device could not be patented, and dropped it into my hands once again. By this time, I was under extreme pressure, as I was once again given the task of pursuing the patent on my own limited funds. At the same time, Puharich and Lawrence kept urging me to give up, saying that they had me beat in the patent office.

In 1964, I was offered a position at Tufts University near Boston. Dr. Dwight Wayne Batteau, a professor at Tufts had an intense interest in the neurophone as it might play a role in man dolphin communications. Dr. Batteau had a small company known as Listening Inc., along with a brilliant electronics man: Steve Moshier. Listening had extensive contracts with the ONR (Office of Naval Research), and was subcontracting Tufts in some of its research and development work.

Our first task was to establish the limits and parameters of the neurophone as it would apply to dolphins. Our secondary task was to determine the physiological mechanism by which the device worked.

Dolphins have extremely large brains, and communicate on many levels. We considered that the neurophone would open a channel to the dolphin which was not previously accessible.

In our initial testing, we found that the neurophone produced a minute mechanical vibration in the skin under the electrodes. When one person was listening to the device, other people standing near the electrodes could hear the sounds coming from the skin. If a stethoscope was placed in contact with the users skin, the vibration could be heard loudly, and clearly. Our initial effort was to determine if this vibration was producing bone conduction, or was the skin vibration merely an artifact?

Doctor Batteau came up with an ingenious experiment to determine if the skin vibration was actually leading to bone conduction: If the neurophone were a separate acoustic channel into the brain, we should be able to play two discordant sounds into the brain of an ordinary person, one by neurophone, and one by earphones through the ears. If bone conduction were involved, the sounds would mix or beat in the bone structures of the inner ear, producing a discord. In the process of bone conduction, sounds are transmitted through bony skeletal structures to the inner ear, where the small bones normally vibrated by the ear drum are activated by skeletal vibration. This vibration is then encoded by the inner ear, and transmitted to the brain by means of the 8th cranial nerve. We are sure that the neurophone did make use of another channel, due to the fact that people with 8th cranial nerve damage had heard with the device.

In our experiment, we played one frequency of sound into the neurophone, and another frequency into the headphones through the ears. If bone conduction were involved, the sounds would mix as predicted in the inner ear, and a discord would be perceived by the test subjects (Tufts psychology students). If the channel to the brain were a separate one, the signals would be heard simultaneously with no discord. At low volume levels, the students were able to perceive the separate sounds with no mixing. At higher volume levels, a mixing could be heard.

We then ran the same experiment by playing the sounds through stereo headphones, with each signal going into separate ears. The results were exactly the same as the neurophone experiment. At low volume levels, the signals were indeed perceived apart from each other. At higher volume levels, the discord could be perceived.

The higher volume discordant mixing can be explained by neural intermodulation possibly taking place in the corpus collosum, the small nerve bundle which connects the left and right hemispheres of the brain together. We tested a number of Tufts students, and they all had identical results. Wayne Batteau was so excited, that he suggested we write a letter to Science, for publication. Our letter is duplicated in the appendix.

As the neurophone was now proven to be a separate brain communication channel, Doctor Batteau made an offer for rights to the device. He offered to give me a 1/3 interest in Listening, a 5% royalty, and position of Vice President in charge of research. The idea was to develop the neurophones potential in many areas, including its potential as an interface (electronic corpus collosum) between man and dolphin, and play EEG signals from a human brain into the dolphin; and to reverse the procedure.

Our work was progressing at a satisfactory rate, when tragedy struck Listening. Wayne Batteau died of a heart attack in shallow water while swimming near our dolphin facility on Oahu, Hawaii. When he died, the Navy canceled our contracts and Listening began to fold. Shortly after that, we demonstrated the neurophone to the patent examiner, and the rest is history.

While investigating man dolphin communications, we succeeded in developing a language translator, a device that translated human speech into dolphin language, and vic versa. This development required a thorough understanding of the nature of speech, and information theory. We made many efforts to model the nervous system, and succeeded in demonstrating that the nervous system uses time ratios as major sources of intelligent information. We then began to investigate timing ratios in speech patterns of humans and dolphins. During that period, we found that speech intelligibility was contained in time dominant ratios in the speech waveform. We found that speech quality was contained in dominant frequency ratios. So, the nervous system is designed to recognize two distinct parameters: the time domain, and the frequency domain.

As a result of the knowledge gained in this area, I designed a circuit which suppressed the frequency domain, while amplifying the time domain. This device, was so radical in approach, that I applied for a patent on it as a specialized speech processor. Six months after the patent was applied for, the National Security Agency placed the patent application under a top secrecy order #756,124. The order said that my invention was being suppressed in the interest of National Security. It further stated that I could be tried for treason and shot by firing squad if I revealed its working nature to anyone other than an authorized government representative. In other words they stole it! Needless to say I was very disappointed in the system. It took four year, and three law firms to sue for release of my invention. We won the battle, and the secrecy order was rescinded. Patent #3,647,970 was issued on the 7th of March 1972.

In 1974, two years after I wrote Pyramid Power, we spent the night in the Great Pyramid. A full description of that event will have to wait for the publication of our full length book on the neurophone. (see also "Gods of Aquarius" by Brad Stieger a starseed book) I can say that I had an experience of enlightenment, including a full blown Kundalini Release. After that experience, I became a trance medium. During one of my trances, the message came through that the speech processing patent which was under secrecy so long was in actuality the perfect neurophone circuit. Well, this was a surprise, as I had never tried the circuit in that way. I must admit, I really did not believe it could work as a neurophone. The message to try the speech processor as a neurophone kept coming and coming until I finally decided to try it out. When I tried it, I was in the suprise of my life! It worked! The result was the development of the present neurophone Mk XI, the finest neurophone to date, and it does not require the use of a radio frequency carrier wave.

The clue as to how the neurophone actually works, is contained in the skin vibration artifact which we discovered at Tufts University. The original neurophone used a high voltage amplitude modulated carrier wave to create a molecular vibration in the skin itself. The skin became the diaphragm of a biological electrostatic vibrator. The skin is piezo electric and opto-electric. That is, when the skin is stimulated by an electric field, or by a photon field, it will contract and vibrate with modulation of the field. If it is mechanically stimulated, it will generate its own electric field. In Russia, blind people have been trained to see with their fingertips; and in Czechoslavakia, deaf people have been trained to hear with their fingertips.

The skin is the largest most complex organ of the living system. As we develop in the womb, all organs of sense evolve from the skin. The skin involutes and convolutes to form eyes, ears, etc. Our research indicates that the skin itself has the latent potential of performing all functions of perception.

The neurophone stimulates and develops this latent ability. The skin is the organ which receives the signal from the neurophone, and converts the incoming signal into a modulated molecular vibration which is then interpreted as sound. We could theoretically stimulate the sense of sight in a similar way. As all acupuncture meridians are present on the surface of the skin, we have found that the neurophone stimulation balances all the acupuncture meridians by activating the skin!

The neurophone Mk XI converts incoming non-linear acoustic information into a time domain amplified signal. This signal is then transmitted to a pair of high dielectric constant ceramic electrodes which are placed in contact with the skin of the head. The electric field (approx 20 Volts RMS) interacts with the skin ceramic electrode combination to create a molecular vibration in the skin. This is then interpreted by the brain. The result is a new modality for coupling information to the brain, using the skin itself as the receptor. Bone conduction vibrators will not work as a neurophone, as the vibratory signal is to gross, the skin itself must vibrate in a synchronous mode in accordance with the time encoded information.

Doctor Christopher Hills, in his book Nuclear Evolution states that the skin is a second brain, and is the basic organ of spiritual and psychic evolution. He states that the skin can be trained to develop powers of perception such as telepathy, etc...

The neural information processing system of the human body is apparently extremely sensitive to time domain information. Doctor Batteau postulated that the nervous system incorporates delay line correlation technology to detect time varied information ratios. The neurophone Mk XI processing circuit processes the incoming complex non linear signal waveform, and amplifies the non linearities thus increasing the timing recognition pattern of the signal. In the process, the frequency domain is suppressed. The time rate of change of the incoming signal is thus amplified. This signal is so time dominant, that it can be hard clipped or run through a zero crossing detector without losing any intelligibility.

This time processed signal is then fed to the pair of high dielectric ceramic electrodes. The 20 volt average RMS signal does not require a radio carrier to work. As stated earlier, the original neurophone design had to actually work by brute force, due to the fact that the modulation signal was not processed to increase the time domain signal properties. As previously stated, the original neurophone produced typical voltages on the order of 3000 at a carrier frequency of 50000 hertz. As the skin is piezoelectric, and has a dielectric constant in the range of 12000, the neurophone electrodes are made of a ceramic material designed to provide a maximum impedance match to the skin itself. The entire skin electrode system is a piezoelectric resonator. Note: The ceramic electrodes are fragile and could break if dropped on a hard surface. Be very careful, they are expensive to replace.

To obtain the best results from your neurophone experience, you should spend at least 1/2 hour per day listening to a broad spectrum frequency source in a quiet, relaxing environment. It is best to listen with an increased blood flow to the brain. The preferred position is an inclined plane of 11 degrees with the head down. Testing has shown that most people go into deep alpha within 30 seconds when placed in this position. This state is the most receptive state to listen to the neurophone. The neurophone listener can build his own incline plane from a board six feet long, and at least 18 inches wide. The raised end of the board should be supported at a level of 14 inches above the floor.

The electrodes should be placed on the temples, directly behind and slightly above the eyes. Do not place on the hair. Although the electrodes will work perfectly well without electrode jelly, we suggest the use of EEG type electrode jelly, or KY jelly, as this improves impedance matching to the skin. If you use KY jelly as an electrode cream, smear an even coating over the black ceramic of each electrode, and place the electrodes in contact with the skin. The electrodes may be held in place by means of an EEG type rubber strap, or an ordinary 2 inch ACE bandage may be used.

After the electrode strap is in position on the head, insert the KY coated ceramic electrodes under the strap so the electrodes are held securely in contact with the temples. Later, you may desire to move the electrodes around to experience different sensations. Many neurophone listeners prefer to place one electrode in the center of the forehead, on the 3rd eye area, and to place the other one on the back of the neck, or on the hand or wrist.

The sound source for neurophone listening can be a cassette player, a radio, or a stereo HI Fi system. The neurophone should be driven from a headphone or a speaker output jack. Your neurophone is provided with an audio connector cable with a mini plug on the cassette end, and a 1/4 inch phone plug on the other end. This will fit most cassette players. If you want to drive the neurophone from another source you may have to obtain a different wire. Your local Radio Shack store will probably have the right one.

In using the neurophone, I generally adjust the sound level of the cassette machine to a comfortable listening level as heard through the built in loudspeaker of the machine. I then plug the mini plug into the earphone jack of the player, and plug the standard phone plug into the input jack on the neurophone. Plug the electrode phone plug into the neurophone output jack. Rotate the neurophone volume control slowly clockwise. The switch on the control will turn the unit on. The small LED panel lamp should glow at this time. Slowly turn the control up until you begin to hear the tape from your cassette player through the neurophone electrodes. Depending on the program material to which you are listening, the sound which you first hear through the neurophone will not sound like Hi Fi. This is due to two things: The sound you hear is time domain dominant. 2. As this is a new listening channel, the brain actually has missing processing capability. If we run a frequency sweep of the neurophone while listening, we will find that all of us have certain spectra which are entirely missing from our perceptual ability. That is, in the beginning we may hear a complex sound wave of one millisecond duration (1KHz), but miss entirely a sound of another domain. As we listen through the neurophone, the missing ranges are programmed into the brain. After listening for as little as 30 minutes, the sound begins to take on new qualities. The sound appears to move around in the head, and take on new dimension as we program our psychic brain centers to receive the new signal input. The more the neurophone is used, the clearer it gets. I recommend electronic music tapes in the beginning, such as the astral sound tape.

As the neurophone channel is but one channel into the brain, we have found that supplementing the neurophone channel with the frequency domain input by means of quality headphones is desirable. The reintroduction of the frequency domain through the headphones adds a new dimension of sound to the brain mind input system. The combination of neurophone plus headphone signals provides the best listening combination. For this purpose, the neurophone contains a headphone output jack which will accept monaural or stereo headphones. The second volume control from the left is used to control sound to the headphones. As the headphones are driven by the cassette recorder, the neurophone must be plugged into a speaker or headphone output jack. The neurophone plus headphone adjustment should be made as follows: 1. First adjust the sound level to the electrodes with the headphone control in the off position. 2. With the headphones in place, slowly adjust the level of the headphones to supplement the electrode signal. Sit back, or lay back close your eyes and let the signals carry you away.

In the near future: Source of Innergy will begin to produce cassette tapes designed to be used only with the neurophone. The tapes will cover many different categories from: Psychic Center Stimulation; to Subliminal Habit Modification Programs. We will notify neurophone owners as these tapes become available for purchase.

In the beginning, it is not necessary to use special tapes, as the object is to develop the latent channel through which the neurophone works. This may be done by listening to white noise (waterfalls) or your favorite music tapes. Neurophone stimulated perceptual enhancement occurs with increasing frequency as you use your neurophone. This experience is similar to the meditation experience of transcending. These periods of extremely clarity become more and more pronounced as you put hours on your neurophone. All changes in awareness are not gradual. All progress is in the form of discrete steps. What may appear to be a gradual altering of consciousness is actually a series of graduations. We may plod along thinking we are making no forward progress, and at the point in time where we feel we want to give up we experience quantum leap in awareness. One of the most common awareness changes with the neurophone effect is an increase in telepathic awareness. Although this cannot be turned on at will, instances of its occurrence will increase in frequency as time goes on. Please keep a diary of neurophone hours of listening, and make note of any change in awareness, dreaming, or unusual perception changes.

We would like all neurophone owners to send us a monthly research report or diary of experiences. This is important data which will enable us to share with you all experiences, and tune the neurophone experience. Keep note of your actual listening time, and listening material. If you experience any change in consciousness or awareness record this down. Others would like to share your experience.

Retired Lt. Col. Thomas Bearden is a nuclear physicist from George Washington University. He is one of the foremost experts in warfare strategy, and is an expert in the field of Soviet Psychotronics Research. Tom Bearden and I have made two mind links by means of the neurophone. Details of the brain mind link will be given in a later edition of the Innergy News, or the neurophone research journal. Col Bearden has developed a mathematical formula that indicates that the combined mind power of a group of people will multiply exponentially if these people are linked in a unitary consciousness. A small group of people could actually alter the entire course of mankind in an instant of time, if they were perfectly linked in a unified field of consciousness. Col Bearden believes that the neurophone is the key to linking consciousness. He believes it may hold the answer to solving all the problems of mankind.

This linking could be done in a number of ways. The Soviets have established that an EEG machine of only 16 channels could pick up the entire consciousness of an individual. All that is then necessary, is to feed the data into the mind of another by means of a multi channel neurophone. The neurophone would then become an electronic corpus collosum between the minds of two or more people.

At a given time in the near future, we will notify all neurophone owners to all try to listen to the neurophone at an exact time period everyday. This will be a simple attempt to unify the consciousness of the group. This type of experiment has been somewhat successful in the past, when used with group meditation. It may be that this experiment will speed up the increased awareness brought about by the use of the neurophone.

History of the Neurowave Signal Development

1. A step up audio transformer was attached to a hi-fi amplifier. The output voltage of the audio transformer was about 1,500 volts peak to peak. The perceived sound quality was very poor,highly distorted and very weak. The signal was perceived as being loudest and clearest when the amplifier was over driven and clipped square waves were being generated. The O'scope signal had ringing spikes or oscillations of a dampened wave at frequencies of 40 to 50kHz. (Flanagan, *Life Magazine* 14 Sep 1962)

2. An amplitude-modulated signal was then fed into a high frequency transformer that was flat in frequency response for an adjustable frequency in the 20-100kHz range. The output was a 2,000 volt peak to peak amplitude modulated carrier wave. (Flanagan Patent No. 3,393,279 (1968)

3. The audio signal is pulse width modulated on to a 50KHZ square wave carrier. Output is stepped up to a 50 volt square wave. This signal is applied to the body by means of piezo ceramic disks.(lead zirconium titanate) (Flanagan Patent No. 3,647,970 (1972)

4. The audio signal is pulse width modulated on to a 45KHZ square wave carrier then double differentiated(processed thru 2 differentiator circuits). Output is stepped up to a 60 volts RMS. This signal is applied to the body by means of piezo ceramic disks (Radio Shack Type)(Brass side to skin, red leads connected to circuit).(Info obtained from various researchers)

5. The audio signal is differentiated and passed into a section that clips everything into a series of square waves and then converted to 40 volt pulses which is then run through a zero crossing detector (comparator).The sensor electrodes are one inch diameter plates made from lead zirconium titanate (piezoelectric discs). (Extrema, US Patent No. 4,545,065)

6. Audio signal is modulated on to a 100KHZ carrier and power amplified then sent to an antenna. Those near the antenna percieves the sound if like thru earphones while those further away hear nothing, no contact with the antenna is made.(approx 1970's)Laser Sound System, Inc., 438 W. Cypress, Glendale, Ca 91204.....also Intelectron Corp., 432 W 57th St., New York, NY, 10036)

7. Another unit is based upon a miniaturized hi-power amplifier amplifying the audio information directly, no square waves or carrirers are used. The sensors are piezo-electric transducers on ceramic bases. Good quality sound (not quite high fidelity headphone sound) is experenced coming from the middle of your brain, more or less.(www.throne.com)(GROC BOX(R))

How to use nuro devices:

1. Connect the brass electrode plates (or bare ceramic) ideally to a point above the shoulders. The sides of the neck or about 1-2 cm out on the face from the center line of the ears are good locations.

2. Adjust the sound input device (stereo tape player or CD player) volume to its lowest setting and then increase the volume until it reaches the maximum volume possible without creating any sensation at the point of electrode contact. You should hear an external sound emanating from the location of the electrodes. This is normal.

3. Using ear plugs, close off the exterior ears during the first week of use. This gives you time to turn your brains attention to the interior sound.

4. For the initial week of use it is advised to use music with a wide band of frequency. Classical string instruments with the full range of orchestal sounds work well. Use the device one or more hours a day.

5. After the first week of use switch to whatever learning tapes you wish to use. It is recommended that you use an auto reversing tape player and use it one or more hours per day.

***Life Magazine* (14 September 1962) ~**

Whiz Kid, Hands Down

by William Moeser

The very young man above is standing on his head because he says it helps him think. It evidently does. Pat Flanagan, a 17 year old inventor from Bellaire, Texas, is already nipping at the heels of the venerable 30 and 40 year old scientist and inventors who built the remarkable structures seen on pages 54 to 65. Pat has just perfected a remarkable machine of his own which one day may help deaf people hear and blind people see. It may also earn him a million dollars. Pat treats his imminent collision with success with equanimity, for he reckons and who is to gain say him nowadays that the generation which will take over from the take over generation will find nothing is impossible.

Pat Flanagan is a unique and self spurred teenage boy who has forged his mind and body into the model of a mature and inquisitive scientist. At the same time he reflects the more standard teenage model; he is the twist champion of Bellaire a suburb of Houston a moderate party goer and girl chaiser, the holder of a private pilots licence, and a spectacular gymnast. espite his ability to function in two worlds, Pat leaves no doubt which one he favors. There are far too many kids my age who are willing to just get along. Pat is confident in his ability to do alot more than just get along.

His single minded belief in his abilities began with a compelling dream he had when he was 8 years old. In the dream I was told I had to learn all about physics and electronics, he says. And it told me I should help people. Already an athletic boy able to do 300 pushups a day, he thereupon set out to improve his mind. By the time he was 13 he was repairing television sets during summer vacations, trying to earn money to build an electronic laboratory in his attic.

Pat's restless imagination drove him to tireless sessions in his laboratory. To abet them he solicited a rare favor from his parents and his older brother Mike the privilage to experiment there undisturbed. One weekend last October, Pat started the experiment which led to the development of his particular fantastic machine. Starting with a radio transmitter he had designed himself, he tried modulating its waves to see if he could induce hearing in his nervous systemwithout going through the normal channels of hearing. He hooked his radio to a small transmitter which looked like an earmuff. After 34 hours of work, he stopped up his ears, put the earmuff to his head and found he still could hear.

I ran downstairs to tell somebody anybody. I woke my mom. She just rolled over and said to me, thats nice, Pat, but Ill listen to it in the morning. She did listen in the morning and alot of very important people have been listening to Pat ever since.

Pat calls his device the neurophone and the process it operates by neuroception. Essentially what it does, he thinks, is transmit electrical messages identical to those sounds generate through the bodys nervous system direct to the brain. Hence he can place the neurophones earmuff on someone's spine or solar plexus, plug up his subjects ears, and the person will still hear. Obviously if the neurophone in fact does what it seems to do, Pat has come a long way twoard short circuiting the bodys ordinary sensory processes and giving man, unprecedented access to his brain. Other inventors many with a lot more experience and facilities than Pat have been seeking such a device for years, and Pat explains his success verses their failure as a product of his own vigorous one man approach to science. I believe research in the problem of electronic hearing has been limited because inventors havent been able to use human subjets as guinea pigs. An animal cant tell you just what 'he heard or how clearly he heard it. But I was my own gunea pig and I wasnt restricted by the possibile bad effects, and I got the secret.

There is some question as to just what Pat has got even he has no firm knowledge of why his neurophone works but no question whatever that somehow he has onto something valuable. Several comanies have expressed interest in buying the rights to the neurophone and one Corpus Cristi firm has tentatively offered him a million dollars if the machine can be adapted to send visual images into the brains of blind people. Dr. William O. Davis of Stamford, Conn Hyuck Corporation, a research and development company which is also fascinated by the neurophone says, The ability to detect radio signals in the brain is a remarkable phenomenon. If we never learn more about Pat's invention, even if we never learn why it works, it certainly is a utilitarian breakthru which could help a number of people. Davis, who used to run the Air Forces basic research program, adds, its important to realize that young Flanagan had the necessary intuition to invent his neurophone. You make discoveries intuitively, in the same manner you would paint a picture or write a symphony.

Pat wants to go on to college, but he is worried about fettering his talent: I seek the knowledge college will provide, but I never want to be just satisfied with what someone else has written and done. He hopes, as his skills increase, to probe other recesses of mens mind. I believe someday the entire concept of medical pratice will be changed by electronics, he says. People will be treated electronically rather than with medicine. If God can make the earth and sky and the force that people and trees live, then inventing anything less than this should be relatively simple.

Statements like this one tend to prove a bit abrasive to Pat's classmates. Pats a wise guy, plenty cocky, and sure of himself, one says, but the bad part of it is hes just that much better at anything he sets his mind to do.

Pat claims this reaction does not bother him I want to be accepted, sure, but some people were cutout to go full tilt. Pats hands and mind are always going full tilt of late. The books strewn across his cluttred attic laboratory range from Zen to Karate to electronic jurnals to the Hidden Persuaders. Lights glow from a wave testing machine and he is working on a new way of tuning TV sets.

People think Ive accomplished so much in life, he says. They say what else can you do , and all that stuff. But I know where Im going and I know what I have to do. When I die I want to leave behind something which will greatly affect and help everyone.

The Neurophone Model 50 ~ The Thinkman
Principles of Operation

The Thinkman is the latest development in the series of neurophone devices first invented by Patrick Flanagan in 1959 when he was a prolific young inventor of 14. Since that time, considerable progress has been made in the development of improved neurophone devices, and the thinkman is the fiftieth neurophone system developed by Dr. Flanagan. A full and complete theory of the neurological, physiological and psychological operation of the neurophone is still being pieced together.

How does it work? How is it possible to hear without using ones ears? The current hypothesis is based upon the fact that the skin is embrionically the source of all our human sense organs. In fact, the skin itself contains more sensors, for heat, touch, pain, etc., than any other part of the human anatomy. The human ear evolves embryonically out of the convolutions of the skin of an embryo in the mothers womb. Basically, the skin is the oldest evolutionary nervous system sensor. Since it is the precursor of the ears, the skin should also be capable of hearing and, as the neurophone proves, the skin does indeed have this capability.

Neurologically, the human skin is both piezoelectric and optoelectric. This means that it produces minute electrical currents when vibrated or rubbed. Soviet and Czechoslovakian neurological research has also shown that the skin produces an electric current when stimulated by light.

As long ago as 1785, Charles Augustin DeCoulomb, a french physicist and an early experimenter with electricity, proved that an electrostatic field produces a measurable physical force. The neurophone processes audio information to produce a very weak 20 volt RMS electric field at each of its two transducer disks. This alternating electric field is changed as a function of the time rate of change of the audio signal coming into the neurophone. This minute electrical field actually causes microscopic vibrations of the skin under the transducer disks. Maximum coupling of the electric field to the skin is ensured by fabricating the transducer disks from Zirconium Titanate which possess the same dielectric constant as human skin. If you were to put an ordinary medical stethoscope on the skin next to one of the transducer disks while the neurophone is being used, you would be able to detect the vibrations of the skin created by the tiny electric field of the transducer disk.

Work done by Dr's Patrick Flanagan and Dwight Wayne Batteau at Tufts University during the years of 1964-1968 is the basis of the current theory regarding how the neurophone works. They discovered that the frequency content of the human voice had little to do with the brain's ability to recognize intelligence in human speech. For example, people who have had their larynx removed can use an artificial larynx, a buzz generator or low frequency vibrator held against the side of the throat. Words are formed totally by the action of the jaw, the tongue, the teeth, the glottis, and the nasal cavities. These cavities form a highly variable time delay encoding chamber. They found that the basic audio information which our brains evolved to decipher, the human voice, is dependent not upon frequency but upon the time rate of change nature of a sound caused by time delays imposed by the mouth and nasal passages. The neurophone makes use of these time delay codes by processing the incoming audio signal to remove the frequency component and leave only the time domain, the time rate of change information. This is one reason why the neurophone sounds so scratchy when one first begins to listen to it. Thus, the electronic circuitry presents audio information to the skin in the manner that the skin was originally designed to receive and decode such information eons ago.

But is it certain that the neurophone is not operating by bone conduction as are some other devices available today for listening experiments and enjoyment? A definitive experiment proving that bone conduction is not a cause of neurophonic hearing can be duplicated by anyone with the required simple equipment. This procedure is called the Batteau test, honoring the late hearing researcher, Dr Dwight Wayne Batteau, who developed the test during neurophone evaluation at Tufts University. Two separate channels of audio information are required. One channel goes through a set of ordinary headphones, the other goes through the neurophone. One specific frequency is played through the headphone channel. Another slightly different is played through the neurophone circuitry to the transducer disks. If the neurophone were producing hearing by bone conduction, the two slightly different frequencies would mix in the bone structure of the inner ear producing a discernible beat frequency. With the nerophone, this beat frequency is heard only at very high volume levels in both channels, levels at which the neurophone probably producing bone conduction by the strong vibration of the skin under each transducer disk. However the beat frequency should theoretically be heard at all volume levels and yet it is not heard at normal neurophonic listening levels. The neurophonic experience is therefore probably a new way to hear, using a new channel into the brain: the skin.

The neurophone is an electronic audio information processor designed and sold for experimental and entertainment purposes. The electronic circuitry of the neurophone accepts an input from any audio or Hi Fi system. It converts the audio signal into a digital like low voltage electrical signal that activates two small transducer disks. These two disks or electrodes may be placed anywhere on the bare skin of the listener. When the transducers are in contact with the skin, the audio signal will then be perceived in the persons head. There are no hazardous voltages or currents between the two sensor disks. There are no radio frequency carriers involved in the action of the neurophone. The neurophone thinkman operates from a 9 volt transistor radio type battery which is enclosed in its case.

The audio signal source for the neurophone may be a portable cassette tape player, a radio, or a stereo Hi Fi system. Most modern cassette tape machines and Hi Fi stereo systems have a headphone or external speaker output jack. The neurophone output goes through two 1 inch diameter transducer disks fabricated of Zirconium Titinate which are imbedded in acrylic plastic tiles to protect the brittle disks against breakage. The transducer disks are, nevertheless, still fragile and should be treated carefully because hard physical shocks will break them. If a transducer disk is broken by rough handling, a new set of transducer disks may be obtained from us. Insert the plug at the end of the transducer lead into the jack labeled electrode on the end of the thinkman.

Connect your neurophone to an audio source such as a cassette machine by means of an audio connecting cable. The small plug on your connecting cable will usually fit into the headphone output or external speaker jack on your machine, the other plug on your connecting cable will plug into the audio jack on the neurophone. Before plugging the cable into your cassette jack, adjust the output volume control on your machine to a 50% or higher level to ensure that the signal processor on your neurophone is receiving an adequate signal level. Turn on the neurophone by rotating the volume control in a clockwise direction. The red LED indicator light will glow, indicating the neurophone is on. Place the two transducer disks on the bare skin on either side of the forehead; They may be held in place by the elastic headband supplied with the unit. Turn the volume control clockwise to about mid way. Turn on your audio source so that the signal will now play through the neurophone. Place the electrode disks on the skin of your temples, plug up your ears, and the audio signal should be heard, appearing to exist in the middle of your head. If necessary, adjust the neurophone volume control until the signal is heard.

As you become more experienced in neurophone listening, you will find that you will be able to place the two transducer disks on the bare skin in spots other than the forehead. One neurophone listener reports excellent neurophone listening with one transducer disk on the soft flesh of one leg and the other transducer on the soft skin of the stomach. However, the neurophone must be operated at a higher volume setting to obtain the same level of neurophone hearing under such remote transducer locations. The ability of the transducer disks to function at a location of the skin remote from the head is partially explained by the current operating hypothesis.

If your neurophone begins to sound weak and the red LED indicator on the front panel begins to glow very dimly, replace the battery in the unit. Unfasten the four phillips head screws holding the bottom on the case and remove the bottom plate. Inside, you will find a battery clip and a 9 volt transistor battery. Replace the battery with a fresh one. For best results, use an alkaline battery which will provide more than 10 hours of neurophone use under normal conditions.

The neurophone processes audio information in such a way that the frequency domain is eliminated but the time domain is preserved. Studies with earlier versions of the neurophone by Tufts University for the US Navy as long ago as 1966 indicated that the brain initially may have difficulty in recognizing the neurophone signals due to gaps in perception. The user may not be able to perceive certain frequencies and time domains in portions of the audio spectrum. As you use your neurophone, these holes in your neurophone hearing process will disappear, as your brain learns to recognize these energies, and you will begin to hear neurophonic sound with full frequency and wide dynamic range.

The neurophone is an experimental listening device that may by continuous use stimulate and enhance dormant perceptive abilities in the user. For example, since the device is apparently stimulating pathways to the brain that are not used normally, it may increase intelligence, telepathic ability, and neural efficiency. Dr. Flanagan has used the neurophone longer than anyone in existence, and has developed extremely high neural efficiency scores. He believes this increase in brain efficiency is directly related to the use of the neurophone device. Many long term neurophone users report increased awareness, telepathic ability, out of body experiences, better memory, and increased auditory frequency range. A commercial pilot from Saudi Arabia reported a recovery of hearing damage due to aural trauma resulting from the loud aircraft engine noise as a result of his job. Please note however, that the neurophone is an experimental device, and has many uses that have been untapped. The neurophone owner will have to experiment and discover his own uses for the device. Dr Flanagan used his own neurophone to learn the Arabic language; actress Susan Strasberg found that she could learn her stage lines easier by playing them through the device. A recent book by G. Harry Stine, titled THE SILICON GODS by Dell, discusses the possibility of using the neurophone as a part of a mind computer link in which the power of the human mind could be amplified by millions of times. Stine says that the entire process if feasible right now, with the help of the neurophone and state of the art brain scan technology. Tom Bearden, in his book EXCALIBER BRIEFING says that the neurophone may eventually be used to successfully enable one or more people to do a perfect mind link in which the power of multiple minds may solve all world problems.

We hope that neurophone owners will join us in the task of discovering and using the potential of the device. The field of neurophone research is wide open, in the future we will see the development of neurophone software and hardware as well as neurophone user's league, our own neurophone magazine, and a host of other neurophone support devices. We invite all neurophone owners to share their experiences with us, so that we may share them with others.

TECH DATA: Model 50 ~ US Patent # 3,647,970

Input impedance: 5000 ohms
Max output voltage at disks: 20 volt RMS>
Battery: 9 volt
Battery life: 10 hours Alkaline cell
Output: Up to 12 pairs of disks
Control: Transducer volume
Operating temp: -40 to +120 F
Dimensions: 4 3/4"x 2 1/2"x 1 1/2"

The Pacinian Corpuscle

The skin contains many energy sensing mechanism, one such mechanism is known as the Pacinian Corpuscle. The PC is a special nerve ending that transforms mechanical vibrations or pressures into nerve impulses. Until this year, (1980) very little was known about thie transducer, and it was thought that the device could only work at low frequencies of stimulation.

Recent research by Fernando Grandori and Antonio Pedotti of Milan, Italy has shed a whole new light on this mechanism. (*IEEE Transaction on Biomedical Engineering,*, Vol BME-27, #10, Oct 1980) It now seems that the PC can react to very high frequencies, and responds best to a square wave stimulus.

The PC consists of a sensitive nerve ending surrounded by a cylindrical-like core structre consisting of closely packed membranes called lamellae. The core is surrounded by a second set of lamellae, in which the distance between each one increases from the innermost lamella toward the periphery of the corpuscle. The space between all the lameae is filled with a liquid whos mechanical properties can be considered similar to that of water. When a displacement of the outermost lamella is caused by exerting an appropriate pressure, this stimulus is transmitted to the core, and in turn, causes a compression of the innermost lamella. This system acts as a differentiating mechanical amplifier.

What is significant here, is that the PC responds best to a Squarewave. The above paper reveals that rate of change is more important than the amplitude of the pressure applied to the corpuscule. This indicates that this highly refined receptor is designed to detect time significance first, and pressure significance secondly.

If we take the Neurophone electrode disks and feed a 50 volt sine wave audio signal into them while placing them on the temples, the signal will be percieved weakly. If we feed the same signal as a square wave, the percieved is 10 times as loud as the sine wave. This tends to substantiate Dr Flanagan's theory reguarding the Neurophone perceptual mechanism as being timerate of change encoded.

PC are located over the entire skins surface, with greater concentrations on the fingertips and sexual organs. In 1981 Dr Flanagan intends to develop research projects which will be able to evaluate the PC theory.

Neurophone Breakthrough

A Possible Mechanism for Neurophonic Action

The Neurophone is a new electronic invention that may enable us to hear by a completely new information channel to the brain. Ordinary hearing is the result of the stimulation of bones in the inner ear by means of vibration. Sound waves may reach these bones through ear canal via the ear drum, or by bone conduction in which sound waves are conducted to the inner ear vibrations in the crainial bones.

When the sound waves reach the inner ear, a vibration is set up in the cochlea which then converts the waves into nerve inpulses that travel up the 8th Crainial Nerve to the sound recognition centers of the brain.

In 1958, Dr Flanagan, then a child of 14 developed a radio transmitter that made the brain into a radio reciever. This device transmits acoustic information to the brain by means of radio waves into the skin, bypassing the 8th Crainial Nerve. When he applied for a patent on the device, the patent examiner rejected the whole thing saying that such a device would go against all known laws of science. ver the following years, Dr Flanagan fought against insurmontable odds to prove that the device did indeed work. In the meantime, LIFE magazine ran a major article on Flanagan and the Neurophone, naming him as one of the top ten scientists in the US at the age of 17! In a final desperate move Flanagan flew to the patent office with a model of his invention and successfully demonstrated the device on a deaf employee in the patent examiner's office. The deaf man heard music for the first time in 15 years and broke down into tears. The examiner declared that the Nurophone was indeed a basic patentable device and approved the patent for release. Patent # 3,393,279 dated 16 July 1968..........

In the years that Dr Flanagan fought to recieve deserved recognition by the patent office, he grew into manhood and was working on Man-Dolphin Communications for the US Navy when the patent was finally issued. While involved in Man-Dolphin research, he became interested in nerve signal information encoding, and began to develop electronic circuits that duplicated the process of pattern recognityion observed in the human nervous system. This work led to research in Cryptography. During that period he developed a top secret sound scrambler that was virtually impossible to decode. Part of the scrambler was based on his research into nerve encoding.

Dr Flanagan believed that the pattern of nerve encoding used in the human speech recognition system could be used to make a better Neurophone. He succeeded in perfecting an electronic curcuit that he believes duplicates the precise encoding of the Cochlea and 8th Crainial Nerve. When he applied for a patent on the new circuit, the patent aplication was immediately placed under top secrecy by the National Security Agency. The only explnation given at the time was that the circuit had potential uses in the defense of the country. Dr Flanagan was happy that the government considered that his device could be used in his country's defense. The only problem was that the government wanted the devise free, and he spent 14 years on it.

He hired attorneys and challenged the secrecy order for over five years. At the end of that period, the patent was released from secrecy and was approved for issue by the patent office. Patent # 3,647,970 dated 7 Mar 1972.

Dr Flanagan then perfected the circuit for another five years. This circuit recognizes time-relationships in the signal waveform, and generates a square wave that is time encoded. Dr Flanagan believes that the nervous system uses a complex deley line time recognition computational system that recognises time information. (50KHZ square wave pulse width audio modulation with double differentiator output)

In July of 1978, he successfully applied the Time Recognition Processor to his Neurophone. When an audio signal is processed through his circuit, it is converted into a form which he believes is an electronic analog of the nerve signal released from the human cochlea, but with one major difference; in the cochlea hundreds of nerves carry the time-encoded signal to the brain. In the case of the Neurophone, the full signal processing is complete and may be carried to the brain by alternate pathways. Through the skin itself.

In the original Neurophone, a 3000 volt amplitude modulated radio wave carried the signal to a pair of insulated electrodes that were placed on the head of the subject. In the present Neurophone, the voltage has been reduced to a 50 volt (maximum) square wave. This signal is applied to the body by means of ceramic disks.(zirconium titanate) The ceramic disks allow the energy field to affect the skin without a current flow. The small electric field causes the skin to vibrate internally in rhythim with the stimulation. The intea-dermal vibration can be heard by others if they place there own ears near the point of electrode skin contact. The vibration is not powerful enough however, to vibrate the bone below the skin surface.

For the past year, Dr Flanagan has been developing a theory which would explain how the Neurophone actually works in the body. Some mechanism must exist that transmits the information from skin to the brain.

The Neurophone has been out now for nearly five months, and we are starting to get reports back from layman and professional users. The inital results are exciting. Several people have reported that their ability to remember data is increasing. People who could not remember telephone numbers are becoming walking phone books!

The first professional research report has been written by Dr Sheldon Deal, D.C., N.D.; of Tucson, Az. Dr Deal is director of the Swan Clinic, and is current President of the International College of Applied Kinesiology.

Dr Deal's preliminary Neurophone research paper was recently presented at the I.C.A.K. convention in Detroit. With Dr Deal's permission, we are publishing his entire paper in INNERGY NEWS.

Neurophone Extract from T.E. Bearden's Book *Excalibur Briefing*

Another device that uses the new hyperspatial, virtual state, nested modulation technology (and has done so for 17 or 18 years) is Dr. Pat Flanagan's neurophone. With brilliant insight and intuition far beyond that of science at the time, Pat invented and patented the instrument by the time he was seventeen years old. The neurophone is a device that, contrary to all present theory and knowledge, will directly pump the brain and reproduce sound and information directly in the brain and mind system, without going through the auditory system at all. A simplified diagram of Pat's improved neurophone is shown in the figure.

Briefly, the device takes a complex signal, such as the sound of an orchestra playing a musical interlude, and electrically processes it as shown in the figure. First the signal is passed into a section that clips everything into a series of square waves, remarkably analogous to the sort of clipped waves Lisitsyn confirms are the information carriers of the human brain. Next the square waves are differentiated, ielding a series of sharp spikes (note that these spikes retain the pulse time content of the clipped signal). These spikes are again differentiated, and since these are finite spikes with real nonzero rize times and decay times rather than theoretical constructs, a series of noisy spikes results from the second differentiator section. From here, the noisy spikes are introduced to special contact electrodes, one of which is normally placed on the forehead, while the other may be placed almost anywhere, including on the foot. Nowhere are any sound waves introduced to the head.

The square wave clipper section reduces the complex signals, their overtones, and their complex modulations to square waves, retaining the temporal content of the wave mix but not the waves themselves. The first and second differentiators highten or filter through the temporal content of the higher order differentiations, that is, they serve as a band pass filter unit to accent the time keying of the neutrinic and mind field portions or aspects of the signal. When these time spikes are then introduced across the body as pulsed voltages, they are modulated directly on the dendrite firings of the brain and nervous system, providing direct and pulsed modulation of the neutrnic and mind field component channels of the mind brain consciousness life loop itself. Thus the neurophone directly inputs information into the brain and nervous system, bypassing all the normal sensory systems that lie between the mind brain loop and outside environment.

(8th Edition, 1980)

Chapter 3

Authors Background, The Neurophone

In 1958, when I was fourteen years old, a close friend of mine, Lou Macko, a television repairman in Houston, Texas told me of a most unusual phenomenon. He told me of a device that would transmit sound to the brain without using the ears.

The description of the device had been given to him by a complete stranger when he had visited Chicago. The device consisted of two copper mesh scrub pads with wires attached to them. The pads were placed in a pair of plastic bags to act as insulators. The wires were then connected to the high voltage side of an audio output transformer which was connected back to back with the output of an ordinary record player.

The result is shown in the figure.

The voltage from the Hi Fi was stepped up a bit and applied to the pads. If the pads were placed on the skin of the head in the vicinity of the temples, one would "hear" the sound from the Hi Fi as if it were coming from within the head itself.

The item at that time had no practical advantage as it was extremely distorted. A good deal of the sound seemed to be missing as if it were cut off.

I researched at the library and discovered the phenomenon was known as far back as 1800 and was discovered by Volta. It was called electrophonic hearing. It was believed that the phenomenon was merely the action of the muscles being electrically stimulated and affecting the bones in the ear by means of minute muscle vibration.

I examined the signal from the device by oscilloscope and discovered the sound came through in a blast when the transformer was overloaded and produced a sharp spike or ringing on the wave form. I soon discovered that the real information was coming through only when this effect occurred. This explained why only parts of the music and voice came through.

I reasoned that the true carrier of information was a radio signal due to the oscillation produced by shock excitation of the combined circuit of the transformer and the parallel tuned circuit formed by the electrodes and the human body. I started experimenting with the unit using a high frequency oscillator of my own design and discovered a resonance in the circuit around 40,000 cycles per second. I soon found that the resonant frequency would change abruptly with emotions and general body changes. The capacitance of the electrodes, therefore the dielectric constant of the skin, changed abruptly from the slightest outside stimulus. The dielectric constant of the skin would change by several orders of magnitude in a fraction of a second! After preliminary measurement of parameters, I designed the original Neurophone which is illustrated in my patent on the device. (#3,393,279)

The device was essentially a high voltage frequency modulated radio transmitter of low power. Its frequency was adjustable to correct for changes of resonance. The original unit was hand adjustable. Later units were automatically tuned for maximum resonance.

The addition of the resonant radio carrier wave made the difference. The sound from the device was fantastic, like sound from another world. The normal frequency response of the ear was extended beyond normal boundaries and there was no distortion.

I began experimenting with a number of people who were considered to be totally nerve deaf, that is, they were unable to hear anything, even with what is known as bone conduction. The results were spectacular. People who had not heard in years were now hearing sounds they only dreamed of ever recapturing. A patent was applied for, and my research continued.

The press learned of my discovery and articles appeared on the front pages of 300 newspapers, and it was picked up by news syndicates and international magazines around the world. LIFE did an article in Sept 14, 1962 page 69, 72. The results were as spectacular as the discovery. We received hundreds of thousands of letters from all over the world. Letters came from as far away as Tasmania addressed only to Pat Flanagan, Inventor, Texas, U.S.A. The U.S. Postal service did a spectacular job in getting the mail to the right party.

There were many Neurophone discoveries not made public. On occasions the device stimulated perfect telepathic contact between one or more persons, often with startling results. These telepathic incidents were kept under wraps for fear of ridicule.

As a result of his research, Dr Flanagan has designed the ideal meditation environment. This environment is a special room shielded from electromagnetic pollution. In this room are placed: an ERG (earth resonance generator), Ion Generator (caution-some ion gen produce pollution as well), an 8HZ pulsating high voltage field (sync to the ERG), and a Neurophone.....

Patrick Flanagan's Neurophone --- Hope for the Deaf and Superlearning for All

by
Eddy Taylor

In 1958, Dr. Patrick Flanagan invented the Neurophone in Bellaire, Texas when he was 14 years old. This electronic device transmits sound through the skin, by-passing normal hearing. A family friend who was a patent attorney for Shell Oil, helped Patrick submit a patent application. The patent examiners thought that this was just sound transfer through bone conduction and refused to issue a patent for 12 years. In a rare meeting in 1970, the patent office agreed to examine the Neurophone for themselves and meet

Patrick and his attorney. They both encountered a surprise. The examiner had a deaf employee attend the meeting to test the device. The man was totally nerve deaf in one ear and almost totally deaf in the other. Patrick showed him how to use the Neurophone and played a record of the famous Maria Callas singing an opera. As he was able to hear the undistorted beauty of her voice, the tears of joy streamed down his face.

For the first time in history the Patent Office reopened a file after it was officially closed and Patrick Flanagan received United States Patent Number 3,393,279. Prior to this, scientists thought that sound could only be perceived by the inner ear to the brain.

A Houston Post reporter had a relative who was nerve deaf from spinal meningitis. A test was arranged and when the device worked, an explosion of news coverage resulted in the story being carried on the international wire services.

How the genie was lost ~

In an agonizing infringement, a Defense Intelligence Agency sealed the patent and a national security order forbade Patrick from working on, or even talking about this invention. After many years and nearly 300 inventions later, Patrick received the Neurophone for public use. In a triumphant court case, the secrecy and the seizure of the device, by the Government Agency, was overruled and the genie was out of the bottle!

Electronic hearing and telepathy ~

To quote Patrick's Neurophone article in Nexus Magazine-Feb/March 1994, "All hearing aids stimulate tiny bones in the ear. In order for bone conduction to work, the cochlea or inner ear that connects to the 8th cranial nerve must function. People who are nerve deaf cannot hear through bone conduction because the nerves in the inner ear are not functional. A number of nerve deaf people who have had the entire inner ear removed by surgery have been able to hear with the Neurophone.

The Neurophone is really an electronic telepathy machine. Several tests prove that it bypasses the 8th cranial nerve or hearing nerve and transmits sound directly to the brain. This means that the Neurophone stimulates perception through a 7th or Alternate Sense!"

The Texas home of the Neurophone ~

The Neurophone became publicly available on a broad scale for the first time in July, 1996. An international Health Products company is now distributing the Neurophone. This corporation is based in Dallas, Texas and was established in 1976. A digitally computerized model is now being developed by Patrick and his wife Gael Crystal in their laboratory in Sedona, Arizona.

Turning on our neurophysiological potential for health, knowledge and awareness ~

One of the last statements by Nikola Tesla, inventor of alternating current, the radio and holder of well over 1,000 patents, was that he regretted not having done more in the science of electromedicine. In 1962, Patrick predicted that electromedicine would revolutionize conventional health care. One of the relatively unknown, silent revolutions has already taken place in the form of blood and lymph cleansing devices. These simple, yet powerful, electronic devices have been popularized by Bob Beck, physicist and bio electronic researcher and Hulda Clark, N.D.

In 1990, a remarkable discovery was made by Steven Kaali, MD and William Lyman, associate Professor of Pathology at Einstein College of Medicine in N.Y.C. It was shown that a minute current (50-100 micro amperes) can alter outer protein layers of the HIV virus and prevent it's attachment to receptor sites. (Science News March 30, 1991, pg. 207). The viruses loose the ability to make an enzyme crucial to their reproduction. This process may also reverse Epstein Barr (Chronic Fatigue Syndrome), Hepatitis and Herpes B. Responsible users of this technology who are HIV positive, may expect a Negative P24 surface antigen or PCR test (no more HIV detectable in blood) after 30 days. A simplified version of this unit now makes self help feasible. The potential to clean and potentize the blood banks of the world with this instrument is truly staggering. Bob Beck's Sept. 96 Explore Magazine Article notes a study on the life span of blood cells sealed under cover slips on microscope slides. While the average life of "normal" blood is about 4 days; blood cells treated with a mild microcurrent live for well over a month!

This very mild charging of the blood does not harm blood cells. Furthermore, the applied physics of Eddy Current (Lenz's law) demonstrates the neutralization of a myriad of parasites, viruses, microbes and fungi. It is important to realize that these organisms are critical co-factors, if not actual carriers, regarding the multitude of new deadly contagious diseases appearing throughout the world.

These blood cleansing devices are safe, with intelligent use, have been around for decades, and seem to have a variety of other benefits. You can do your own research on the scientific evidence by scanning (http:/www.electriciti.com/explore/Articles/Beck/HIVArticle.html). Be aware that there are now customized, blood and lymph cleansing units far better than Mr. Beck, Dr. Clark, and most others, describe and or advertise.

The big turn off ~

By contrast, the HAARP Project, a giant array of microwave towers in Anchorage Alaska, may not exactly raise awareness and improve human health. It's billion plus watts of power can impact an entire nation or even a complete hemisphere of the world. You may find the rest of the story through the writings of Nick Begich and other investigators. This brings new meaning to that old expression used in T.V. and Radio, "Don't touch that dial!" Nick is a life long educator, native of Alaska, and has been featured on thousands of radio programs in the last 4 years. He also is perhaps the most informed writer on the Patrick Flanagan story and the benefits of the Neurophone.

Education Automation Vacation ~

Scientific experiments indicate that effects of the Neurophone range from super learning, long term memory speed learning, relaxation, pain control and enhanced psychic abilities. The Neurophone's ability to transfer large amounts of information into long term memory may, alone, make the current model of education obsolete. We could advance beyond the problem of information overload and actually emphasize values, goals, strategy and a profound interdisciplinary approach to world problems. Positive solutions in an ever more complex world may themselves depend on the solution offered by the responsible use of the Neurophone.

Ma Bell ~

Studies on a special "head start" program, with pregnant women using the Neurophone have promising news. These women describe children with marked intelligence. This neuro-networking seems actually to nurture neuropathways for the fetus.

Extra sensory perceptions ~

All organs of perceptions evolve from the skin of the child within the womb. Theoretically, the skin could perform all sense perception. In Russia blind people have been taught 'to see' with their fingertips. Deaf people in Czechoslovakia have been instructed 'to hear' with their fingertips.

Details on the Neurophone, super learning and electromedicine ~

The intricacies of how the Neurophone is constructed, along with it's bio-physical- interactivity, is provided in the book, *Towards A New Alchemy*, by Nick Begich. For a broader background see *Super-Memory: The Revolution*, by Sheila Ostrander and Lynn Schroeder. The Explore More Magazine's March/April 1996 article, 'The Skin, Our Fifth Sense' is a real eye opener. For a historical view of related research read *Psychic Discoveries Behind The Iron Curtain* by Sheila Ostrander and Lynn Schroeder. A technical understanding of the bio-electronics of organisms in health and disease, will be found in the book, *The Body Electric- Electromagnetism and the Foundation of Life*, by Robert O. Becker, M.D. and Gary Selden, (Quill Publisher).

Dolphin speak ~

In a curious parallel to Roxanne Kremer's work on interspecies communication with the Pink Amazon River Dolphins, Dr. Flanagan has made impressive technical contributions. In February, 1968, he applied for a patent on a device for translating human speech into dolphin language and vice/versa. This was a result of studies with dolphins in the lagoon of a small island off the coast of Oahu, Hawaii. A vocabulary of 30 words was discovered before a startling intervention. Six months after applying for the patent, it was placed under secrecy order #756, 124 by a U.S.Government surveillance agency. Five years later, another hard-fought legal battle rescinded the suppression and patent #3,647,970 was granted on March 7th 1972. This speech processing patent is actually used as the circuit in the present version of the Neurophone.

The sound of the new millennium ~

"The Music of the Spheres and the Hemispheres", heard with the assist of the Neurophone, opens new doors for musicians and composers, as well as educators and students of life in general. In what may be seen as another motif on Sonic Bloom-like-phenomena, some theories hold that it has the potential for developing super plants and healing animals as well as people.

Mind meld ~

Experiments with a Neurophone mind link between two or more people seemingly makes possible learning directly from the mind of another. And I thought this was only in the SCI FI domain of Star Trek's Mr. Spock and certainly beyond the ken of Dr. Spock. Nick Begich describes the phenomenon as an electronic 'corpus collosum' between the minds of 2 people. The corpus collosum is the semi-permeable bridge between the 2 hemispheres of an individual's brain.

The Neurophone and other gems ~

The Neurophone also causes both sides of the brain to pulse in harmony creating an environment which may be ideal for learning. Use of the Neurophone tends to balance all the acupuncture meridians. In the near future the Flanagans will produce cassette tapes and CD's designed to be used only with the Neurophone. The tapes will cover categories as varied as Psychic Center Stimulation to Subliminal Learning Programs.

Other Flanagan products include Crystal Energy, (ultra colloidals --- each only 12 atoms wide --- of silica, magnesium, zinc, gold, silver, and titanium which have duplicated the structure and improved upon the health benefits of Hunza Water). The people of Hunza claim that their longevity, often living up to 130, stems primarily from their consumption of Hunza water, also known as 'glacial milk'. This technology has also been used to create what is truly the most unique spirulina, and other supplements, presently known.

A word to the wise: Winston Churchill said, "Most people occasionally stumble over the truth, but most pick themselves up and continue on as if nothing had ever happened". If you sense you've encountered some truths in this article don't use them as stumbling blocks. They may be stepping stones to far higher truths, if you dare to care and share. Data in this article can be legally offered only as "theoretical"; and no medical claims can be made or implied. See your health professional...

Nervous System Excitation Device

Gillis Patrick Flanagan

This invention relates to electromagnetic excitation of the nervous system of a mammal and pertains more particularly to a method and apparatus for exciting the nervous system of a person with electromagnetic waves that are capable of causing that person to become conscious of information conveyed by the electromagnetic waves.

It is an object of the present invention to provide a means of initiating controllable responses of the neuro senses without applying pressure waves or stress waves to the ears or bones. Another object of this invention is to provide a means of causing a person to receive an aural perception of the sound corresponding to the audio modulation of radio frequency electromagnetic waves that are coupled with the nervous system of the person. These and other objects of this invention will be understood from the following drawings and description of the invention, wherein:

Figure 1 is a schematic illustration of one form of the present nervous system excitation device.

FIG.3.

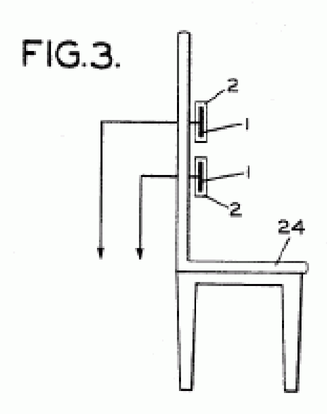

Figure 4 is a diagrammatic view illustrating another form of field generator adapted to be used with the device of Figure 1.

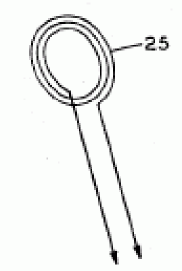

FIG.4.

The present invention involves the discovery that certain electromagnetic waves induce responses in the nervous systems of mammals. In human beings a response is produced when some or all of a person's nervous system is placed within a field of electromagnetic carrier waves of such a frequency, the nervous system is responsive to the modulation of the carrier waves. Each individual nervous system is at least somewhat selective in respect to the frequencies to which it is most responsive. A frequency to which the nervous system of a person is demonstratively responsive can be determined by varying the frequency of carrier waves that are modulated by an information signal, such as speech or music, and measuring the frequency of such waves that produce the sensation of hearing the sounds corresponding to the modulating signal.

In the method of the present invention, a response is initiated in the nervous system of a mammal by disposing at least a portion of that nervous system within a field of electromagnetic waves of a frequency above the aural range. In a preferred embodiment of this invention, at least a portion of the nervous system of a person is exposed to audio modulated electromagnetic waves having a radio frequency such that the person experiences the sensation of hearing, substantially free of distortion, the information which is conveyed by the audio modulation.

The present invention may be used as a hearing aid, as an aid to teaching speech to a person who was born deaf, as a means of communicating with persons in locations in which the noise level is high, as a device by which a person can listen to an audio signal that cannot be heard by others, etc.

As shown in Figure 1 of the drawing, in a preferred form of the invention, a field of electromagnetic waves is generated by a field generating means, such as a pair of electrodes 1. The electrodes 1 are preferably electrically insulated, for example by surrounding them with a suitable electrical insulating material 2, and are arranged to generate a field coupled with at least a portion of the nervous system of a person, for example by being placed near or along opposite sides of a person's head. The electrodes 1 can be placed in direct contact with the skin and the electrodes can be placed on or near various portions of the body, such portions preferably being near the spinal cord.

The electrodes 1 are electrically connected to a source of modulated electromagnetic waves inclusive of a radio frequency power amplifier and variable frequency oscillator, indicated in box 4, a source of audio signal, indicated in box 5, and a power supply for the signal source, modulator and amplifier, indicated by box 6. The variable frequency oscillator 3 is preferably provided with a manual radio frequency control means, indicated by box 3a. Numerous forms of the components, indicated in boxes 3 to 6, that provide suitable power and a source of modulated electromagnetic waves are presently known and the known devices can be suitably used as long as they are arranged to produce a relatively high voltage output that has a radio frequency above the audio range and is capable of being modulated by an audio signal or other signal adapted to be conveyed by the modulation of electromagnetic waves of such a frequency.

The modulation can suitably be effected by means of either an amplitude or frequency modulation of such electromagnetic waves. These waves preferably have a frequency in the range of about 20 kilocycles per second to about 200 kilocycles per second. The output of the source of modulated electromagnetic waves is preferably at least about 1 watt where the field generator comprises a pair of insulated electrodes placed on the head of a person. The extent to which a person is aurally perceptive to the output supplied at a given wattage is materially increased when at least one of the electrodes is placed in electrical contact with the body of the person.

In a preferred mode of operating the apparatus shown in Figure 1, the electrodes 1 are placed on the sides of the head of a person. The source 5 of audio signal is actuated to produce an audio signal corresponding to sounds recognizable by that person, and source 3 of modulated electromagnetic waves is actuated to couple the waves with the nervous system of that person. When control 3A is adjusted so that the frequency of the modulated waves is a frequency to which his nervous system is particularly responsive, the person to whom the field of such waves is applied has the sensation of hearing the sounds corresponding to the audio signal substantially free of distortion.

In the circuit shown in Figure 2, a phase shift type of carrier oscillation, generally designated by dotted rectangle 7, with a frequency control, generally designated by rectangle 8, is arranged to produce electromagnetic waves, shown at A, a frequency ranging from about 20 to 200 kilocycles per second. The oscillator output is coupled through capacitor 9 to a radio frequency power amplifier, generally designated by a dotted rectangle 10. Potentiometer 11, which is connected between capacitor 9 and ground, provides a means of adjusting the input to the amplifier. Switch 12, which is connected to the cathode of tube 13 of the amplifier, provides a means of switching between resistors 14 and 15 to vary the operating power characteristics of the tube.

The output of amplifier 10 is connected to transformer 16 which is coupled back-to-back with transformer 17. This arrangement of transformers provides an inductive load such that the amplifier yields a high voltage output is isolated from other components of the circuit. Resistor 18 connected across the output side of transformer 17 serves to reduce any dangerous voltage spikes which might be produced. The output side of transformer 17 is connected to a suitable field generator, which may comprise the electrodes 1 surrounded by insulating material 2.

The output of amplifier 10 is amplitude modulated by means of the modulator generally designated by dotted rectangle 19. A fluctuating electrical signal B, preferably of audio frequency, is applied to the modulator by means of input jack 20 and transformer 21. The output of the modulator varies the screen voltage of tube 13 of the amplifier so that the modulation envelope of the current oscillations C produced across the load of tube 13 correspond to the fluctuating signal B applied to the modulator.

Potentiometer 22 is connected to the cathode of tube 23 as the cathode resistor of tube 23. Potentiometer 22 is preferably adjusted so that the plate current of tube 13 of the amplifier so that the modulation envelope of the current oscillation C produced across the load of tube 13 correspond to the fluctuating signal B applied to the modulator.

Potentiometer 22 is connected to the cathode of tube 23 as the cathode resistor of tube 23. Potentiometer 22 is preferable adjusted so that the plate current of tube 13 is about half its normal maximum value. The fluctuating signal applied to modulator 19 is then adjusted to cause the plate current of tube 13 to vary between the maximum and minimum values so that a large current variation occurs in the load 16 of tube 13.

The apparatus shown in Figure 2 has been used to communicate speech and music to numerous persons including registered physicians. In these uses the electrodes 1, in the form of circular disc covered by a plastic insulation 2, were placed against the sides of the heads of the persons. When the electromagnetic waves were adjusted to a frequency to which persons having normal hearing were selectively responsive, none of these persons perceived any sensations of hearing or experienced any discomfort when no audio modulation was applied to the waves. When the waves were audio modulated with a speech or music signal, none of these persons experienced any discomfort, but they each had the sensation of listening to the transmitted information and hearing it at least as clearly as they would hear such information from an audible transmitter. When the same apparatus was similarly employed on a person whose hearing had been damaged to an extent requiring a hearing aid to hear normal conversation, that person heard the audio signal (with this hearing aid disconnected) and heard music with a better fidelity than that obtainable with this hearing aid.

Figure 3 shows an arrangement for mounting the field generating means in a position such that a portion of a person’s nervous system may be moved into and out of coupling with the field at the will of the person. In this arrangement, electrodes 1 surrounded by insulation 2 are mounted in vertical alignment along the back of a seating device, such as chair 24. When a person is seated and leaning back in the chair, portions of his nervous system are brought into coupling relationship with the field produced by electrodes 1.

Figure 4 shows an alternative arrangement of the field generating means. In this arrangement, inductive coil 25 is connected to the output of a suitable source of modulated electromagnetic waves and serves as a field generating means which is adapted to be placed around the head of a person.

It is to be understood that the above embodiments and examples have been presented for descriptive purposes and that, within the scope of the appended claims, the invention may be practiced otherwise than specifically illustrated and described.

US Patent # 3,647,970

US Cl. 179/1/5 (5 March 1972)

Method and Apparatus for Simplifying Speech Waveforms

Gillis P. Flanagan

Abstract ~

A speech waveform is converted to a constant amplitude square wave in which the transitions between the amplitude extremes are spaced so as to carry the speech information. The system includes a pair of tuned amplifier circuits which act as high-pass filters having a 6 decibel per octave slope from 0 to 15,ooo cycles followed by two stages, each comprised of an amplifier and clipper circuit. For converting the filtered waveform to a square wave. A radio transmitter and receiver having a plurality of separate channels within a conventional single side band transmitter bandwidth and a system for transmitting secure speech information are also disclosed.

Background of Invention ~

This invention relates generally to electronic processing of speech, and more particularly relates to a method and system for simplifying the speech waveform to facilitate transmission of the speech throughout various media without materially degrading intelligibility.

In the process of producing human speech, the voice box creates a series of sound pulses which reverberate within and are shaped by the upper throat and mouth cavity. The frequency of the pulses produced by the voice box primarily determines the frequency or pitch of the sound, while the shape of the mouth cavity reverberates and shapes the sound pulses to produce the speech information. The resulting speech waveform is very complex and highly redundant. If such a waveform is passed through a band-pass filter having a bandwidth significantly less than 3000 cycles per second, the speech becomes unintelligible. Thus, even the simplest voice communication channels require a substantial bandwidth. Heretofore it has been commonly believed that the speech information was contained in the amplitude as well as the frequency modulation of the speech waveform, When voice sounds are induced in a body of water or the earth, the many reverberations caused by the various velocity discontinuities make speech unintelligible over relatively short transmission lengths. Also, the complex speech waveform has made encoding or scrambling for secure transmissions, either by electromagnetic, electrical, or pressure waves, so impractical as to be very seldom used.

Summary of Invention Claimed ~

This invention is concerned with a method and system for simplifying a complex speech waveform so that it can be used for a multitude of applications. The simplified speech waveform may be passed through a narrow band-pass filter, thus permitting a greater number of communication channels within a given frequency band. The simplified speech waveform can be transmitted directly through the earth or water as a pressure wave and understand, either directly from the medium, or after simple amplification. The simplified waveform can be easily encoded by scrambling to provide secure voice communications. The simplified may be sued to operate machinery, produces more efficient public address systems and transmitters with greater range peak power for a given average power, and thus longer ranges.

In accordance with the present invention, the speech waveform is converted to a signal having substantially constant upper and lower levels with abrupt transitions from one level to the other, the abrupt transitions being in time correspondence to amplitude changes in the speech waveform that exceed a predetermined rate of change. This is accomplished by a system including a high-pass filter and means for converting the filtered waveform to a constant amplitude, substantially square wave.

More specifically, optimum results have been achieved by using a filter having a 12 decibel per octave slope from 0 to 15,000 cycles per second. In one specific embodiment, this filter is formed by a pair of tuned amplifier circuits each having a 6 decibel per octave slope within the frequency range of interest. In this embodiment, the speech waveform is preferably combined with a high frequency noise masking signal of lower amplitude prior to processing.

In accordance with another specific aspect of the invention, means for converting the filtered signal to a square wave comprises at least one amplifier followed by a clipper circuit.

The invention also contemplates a voice communication system having a plurality of separate channels within a bandwidth normally allotted for a single frequency, for example four channels within a bandwidth of 1500 cycles per second. In this system the processes speech is selectively passed through one of a plurality of narrow band-pass filters to a transmitter. The receiver has similar narrow band-pass filters so as to be selectively sensitive to transmissions in that pass band.

In accordance with another specific aspect of the invention, each transition of the square wave is converted to a pulse of predetermined amplitude and width, which is then converted into a plurality of pulses with predetermined time spacing. These pulses are then transmitted to a receiver where the plurality of spaced pulses are recombined as one pulse. The square wave is then reproduced from the combined pulses.

Brief Description of the Drawings ~

The novel features believed characteristic of this invnetion are ste forth in the appended claims. The invention itself, however, as well as other objects and advantages thereof, may bes be understood by reference to the following detailed description of illustrative embodiments, when read in conjunction with the accompanying drawings, wherein:

Description of Preferred Embodiments ~

Referring now to the drawings, and in particular to Figure 1, a speech processor in accordance with the present invention is indicated generally by the reference numeral 10. The speech waveform is applied to the input 12 as a voltage signal derived from a microphone (not illustrated) or other suitable transducer. The speech waveform is summed with a much higher frequency, for example 50 KHz, masking signal produced by the signal generator 14. This signal is passed through a pair of tuned amplifier circuits 16 and 18. Each of the circuits 16 and 18 is a high-pass filter having a 6 decibel per octave slope from 0 to 15,000 cycles per second, thus providing a combined slope of 12 decibels per octave.

The filtered waveform is then passed through a circuit means for converting the filtered waveform to a square wave which is converting the filtered waveform to a square wave which is comprised of a first high gain amplifier 20, a first clipper circuit 22, a second high gain amplifier 24, and a second clipper circuit 26. The square wave is then passed through power amplifier 28 to the output in a form to drive a loudspeaker, transducer, radio transmitter or the like. When ultimately passed through a speaker, or other suitable transducer, the square wave is fairly intelligible. The square wave so produced has constant upper and lower levels, with very abrupt transitions between the upper and lower levels as a result of the two stages of amplification and clipping. The transitions occur in time correspondence to amplitude changes in the original speech waveform applied to the input 12 that exceed a predetermined rate of change so as to be passed through the high-pass filters 16 and 18.

A detailed circuit diagram of the system 1o us shown in Figure 2 wherein corresponding components are designated by corresponding reference numerals. Each of the components is of conventional design. The signal generator 14 has a variable load resistor 30 in the output stage which permits the amplitude of the masking signal to be adjusted to eliminate oscillations caused by noise. The amplitude of the masking signal should not be any greater than is required to prevent oscillation to minimize interference with the processing of the speech waveform. The tuned amplifier circuits 16 and 18 are of identical construction. Each is comprised of an amplifier having a differential input state 32 and a single output stage 34 which drives a tuned filter circuit 36. The tuned amplifier circuits 16 and 18 are coupled by capacitor 38, which of course also comprises an element of the filter. The amplifier 20 is identical to the amplifier portions of the tuned amplifiers 16 and 18, and is coupled to the output of tuned amplifiers 16 and 18, and is coupled to the output of tuned amplifier 18 by capacitor 40. The clipper circuit 22 is merely a diode bridge to the output of tuned amplifier 18 by capacitor 40. The clipper circuit 22 is merely a diode bridge coupled to the output of amplifier 20 by capacitor 42, followed by a filter comprised of capacitor 44 and resistor 46. The output of the clipper circuit 22 is coupled to the input of amplifier 24 by capacitor 50. Amplifier 28 is identical to amplifiers 20 and 24 and is coupled to the output of the clipper circuit 26 by capacitor 52.

In a typical embodiment of the circuit of Figure 2, the PNP transistors may be MPS3640 transistors, and the diodes may be IN914 diodes. The resistors have the following values in kilohms as referenced in circuits 16 and 22: a = 33, b = 33, c = 10, d = 33, c = 0.33, f = 33, g = 10, h = 10, I = 10, j = 100, k = 100, and m = 1.0. The capacitors are 10 microfarads, except for the capacitors in the LC tuned circuits which are 0.001 microfarads, All coils are 10 millihenrys.

The high-pas filters 16 and 18 may be of any suitable conventional circuit design, and may be a resistor-capacitor filter, a shortened delay line filter, or an inductor-capacitor filter, for example. The means for converting the filtered waveform to a square wave may also be any suitable conventional circuit such as a Schmidt trigger, or a very high gain amplifier which quickly saturates.

A multichannel speech transmission system in accordance with the present invention is indicated generally by the reference numeral 60 in the schematic block diagram of Figure 3. In the system 60, the speech processor 10 is selectively connectable to any one of four filters 62-65 by a selector switch 66. The outputs of the filters 62-65 are connected to the input of a conventional single side-band transmitter 68.

The filters 62-65 are narrow band-pass filters of any suitable conventional design having mutually exclusive pass bands of about 300 cycles centered at frequencies f1, f2, f3 and f4, and are grouped within a total bandwidth of about 1500 cycles, for example. Since 3000 cycles is a typical bandwidth for single side band transmitters operated for simple speech transmission, eight filters can be used if desired. The square wave produced by the speech processor10 may be selectively passed through any one of the narrow band-pass filters 62-65 without materially reducing its intelligibility.

The filtered square wave is transmitted by the conventionaltrnamitter68 to a conventional single side band receiver 70.The output of the receiver 70 is selectively connectable through filters 72-75 to a power amplifier 78 by a selector switch 76.The filters 72-75 have corresponding passbands centered at frequencies f1, f2, f3, and f4. The amplifier 78 may drive a speaker 80. Therefore, if the selector switch 76 of a particular receiving set 70 is set to the filter corresponding in frequency to the filter selected by switch 66 in the transmitter, the filtered square wave will be reproduced by the speaker 80 and will be sufficiently intelligible for nearly all voice communication purposes. However, if the selector switch 76 of a particular receiver is set to another frequency filter, no sound is produced by the speaker 80. Thus, the transmission system of Figure 3 provides four separate voice channels within the frequency band of 1500 cycles, or eight channels in the 3000 cycle bandwidth conventionally allotted for single side band operation. Of course,itisto be understood that the particular radio frequency is merely illustrative of the broader concept of the invention and that the same principles can be applied to transmissions through any media by electrical or electromagnetic waves.

A secure system for transmitting scrambled voice communications is indicated generally by the reference numeral 100 in Figure 4. Again the speech processor 10 is used to generate the square wave as heretofore described., The square wave is then passed through a differentiator 102 which produces a sharp spike pulse in time correspondence to each transition of the square wave. The sharp spike pulses have a polarity determined by the polarity of the transition and are therefore passed through a fullwave rectifier 104 which converts all of the spike pulses to the same polarity. The spike pulses are then used to trigger a single shot multivibrator 106 which produces a pulse of predetermined amplitude and time width in response to each spike pulse. The uniform pulses from the single shot multivibrator 106 are then passed through an encoder 108 which produces a plurality of pulses of corresponding width in a predetermined timed sequence in response to each input pulse. This may easily be accomplished by a plurality of parallel delay lines d0, d1, and d2 for transferring the pulses to point 110 at predetermined time intervals. The pulses are then amplified by an amplifier 112 which drives a transducer 114. The transducer 114 may induce the pulses in water, in the earth, or in any other propagating medium. Or, if desired, the transducer 114 can be replaced by a radio or other electromagnetic wave transmitter.

The transmitted pulses are received by an appropriate receiving transducer 116, which reproduces electrical pulses of corresponding width and amplitude. The received pulses are amplified by amplifier 118 and applied to a decoder 120. The decoder 120 is comprised of an identical number of delay lines of identical time relationship so that the three pulses are recombined as a single pulse summation point 122.

Each time that the three pulses occur at the same point in time, the sum of the pulses exceeds the threshold of a detector 124 which triggers a flip-flop 126. The output of the flip-flop is then a reproduction of the square wave originally produced by the speech processor 10. This square wave is then amplified by amplifier 128 to drive a speaker 130 and produce the voice communication. Reproduction of the voice communication can be accomplished only if the receiving decoder matches the transmitting encoder. The encoders and decoders can be easily interchanged in order to maintain secure transmissions.

Although preferred embodiments of the invention have been described in detail, it is to be understood that various changes, substitutions and alterations can be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

[Claims not included here].

Flanagan
Neurophone
DSP

click to enlarge

This fascinating technology was developed in 1958 by Patrick **Flanagan**. It was thought that sound was only heard by the inner ear; **Flanagan**, however, was able to demonstrate that the brain also hears sounds that vibrate on the skin.

To use this technology, you place the sensors on the forehead under a headband. Then plug the unit into your sound source, such as a CD player. The sensors cause your skin, the largest organ of the body, to vibrate to the music you’ve selected, much like a speaker vibrates.

By bypassing the ear, you are using a completely different part of the brain to process the sound creating new neural pathways. This technology is great for concentration while studying, learning languages, assisting in “new sound perception” great for listening to music in a whole new way, helping with meditation, relaxation, and healing.

When you first put the sensors on your skin, you feel a vibration and can actually hear the sound of the music you’ve selected. You can put the sensors on any part of your body, not just the forehead.

Just by wearing the sensors, you will notice a dramatic mood shift making you more positive, and also a change in your brain power, producing unwavering focus! The ultrasound it produces sends high frequency sound waves and their harmonics beyond the hearing threshold to the brain. It is these high frequency sounds that actually energize the brain, giving you more energy and focus. For music lovers, the clarity of the sound will astound you.

There are two products using this technology available, the **Neurophone** and the Echofone. Here are the differences:

Neurophone

Portability makes it useful for: Listening to lectures in the classroom ~ Using at work for powerful focusing ~ Focusing at sporting events

Echofone

Stereo Transducers makes it useful for: Serious musicians learning music ~ Music afficianados to experience incredible listening pleasure Sound therapy utilizing binaural beat frequencies

The **Neurophone** operates on an internal rechargeable battery making it completely portable, not requiring a plug. The internal pink sound generator makes it easy to use on-the-go because you don't need to plug it into a CD player.

The Echofone works in a similar manner, however is not portable. It is ideal however for music appreciation having a convenient control panel allowing you to easily mix the vibration intensity of the sensors with the volume intensity of the headphones.

The New Neurophone GPF-1011 DSP

Dr. Patrick Flanagan's revolutionary ultrasonic neural stimulation instrument for brain entrainment, aiding in learning, relaxation and meditation

The NEW Neurophone® Golden Ratio Series is here!

The Neurophone® marks a culmination of innovation and engineering spanning 45 years. The GPF-1011 DSP offers a refined aesthetic design and advanced microprocessor control to create the finest experience in ultrasonic neuropathic stimulation. The Neurophone® is a precision scientific instrument with an extensive digital signal processor that encodes sound and modulates it into ultrasonic signals. The GPF-1011DSP offers the first, all digital Neurophone®. This profound digital engineering offers a quality of ultrasonic transmission that is more accurate and rich in harmonics than an analog representation, offering a more enriching and stimulating experience. Exciting new University studies are underway evaluating the Neurophone's® profound role in accelerated learning and memory retention. This instrument represents my life's work and I am greatly pleased to offer the new Neurophone® Model GPF-1011 DSP.

Another Look at the Neurophone

by

Rick Andersen

(6/21/97) Freely distributed for informational purposes

Dr. Pat Flanagan's Neurophone, in its several versions, has been the subject of intense interest to many experimenters. Later embodiments of his device appear to be based on the observation that our neural systems are set up to receive and decode external stimuli as sharp, transient spikes which represent a conversion of smoothly-varying analog sound pressure waves into time-coded "digital" nerve impulses. The associated propagation delays most likely do with sound what our TV screens do with serially-sequenced video waveforms: Convert them into a spatial distribution across the TV screen as a picture (sound waves encoded spatially across the brain cortex as a spatio-temporal pattern). The Neurophone is a first attempt at performing this complex conversion from frequency- to time-domain.

The idea of reducing full-fidelity speech/music into a differentiated, time-ratio coded version has many potential applications such as:

* Compression of audio or other analog signals
* Artifical cochlea for "androids"
* Alternative sensory stimulus ("hearing" through the skin) a la Neurophone
* Induction of information to the brain without contact (e.g., sharply-pulsed magnetic fields around the head such as Persinger's work

After reading the many files available on the Neurophone's history and many embodiments, as well as building a few experimental circuits myself, I've come to the conclusion that the simple "clipper/double-differentiator"-type circuit, as described by Tom Bearden in his book "Excalibur Briefing", is lacking as an effective way to convert sound to time-coded pulses, for the following reasons:

All sound waveforms (other than pure sine waves) are complex superpositions of several frequencies -- fundamentals and their harmonics, if they're periodic (pitched) sounds. The "tone color" is heavily dependent upon the relative amplitudes of the harmonics vs. the fundamental frequency.

Vowels, or diphthongs, in spoken language, are essentially very specific bandpass-filtered spectra. The vocal cords produce a harmonic-rich, raspy buzz, analogous to a sawtooth or pulse wave as seen on an oscilloscope. The mouth and nasal cavities act as resonators to selectively filter the buzz from the voice box into recognizable vowel sounds. "Fricatives" such as the "ssss" sound are unpitched bursts of air, "filtered" through the teeth, lips, etc. Fricatives contain many high frequencies clustered around 6-9 KHz, whereas a male voice is usually pitched (fundamental) around 200 Hz.

To run such a waveform into a clipper or squaring amplifier (comparator, Schmitt trigger) would be to take a very crude zero-crossing detection; the frequency with the largest amplitude is the fundamental... the higher harmonics "ride" upon it... so the fundamental is the frequency that gets to "call the shots" with the zero-crossing detector. So out comes a square wave, switching up or down through zero only at the grossest points of change along the waveform. We've already "hacked off" most of the "details"-- the information contained in the upper harmonics.

Now if we differentiate, and then "double-differentiate" this clipped wave, we will get narrow pulses which "track" the edges of the original complex sound wave ONLY WHERE IT CROSSED THROUGH ZERO on the scope. The problem is, we've clipped all the good stuff -- the harmonics -- off, and lost much of the information in the process. The speech now sounds like a person talking through a "kazoo" -- amusing, but not very useful.

How do we make square waves, and then narrow pulses (differentiated), out of a complex wave in such a way as to preserve DETAILED variations (upper harmonics)?

INTEGRATE, COMPARE, DIFFERENTIATE, and SUM

The method I am outlining here is a result of my own brainstorming on the problem; if I have stepped on anyone's feet by re-inventing your ideas, my apologies, but rest assured that I'm not looking for patent rights, just circuit functionality. Maybe I've discovered Flanagan's REAL method???...

First, we need to appreciate the fact that there are millions of neurons doing their thing in our auditory system, not just a few. Accordingly, I'm going to outline a simple circuit that will produce time-coded spikes, but I'm recommending that several of the circuit modules be built and chained together SEQUENTIALLY (analog sections), with their differentiated SPIKE outputs all SUMMED together and perhaps clipped as a group so that there is one amplitude for them all, but varying repetition rates -- sort of like Pulse-Position Modulation but more complex. This is the output that will connect to the piezo skin transducers after suitable amplification.

The cochlea has many, many neurons working on a serial sound "stream" at the same time. Some are positioned "up front" where the sound enters from the outside, some are down the trough a ways, and some are located at the far end. As such, there is a built-in time delay, or acoustic propagation delay, from one end of the membrane to the other. Carver Mead at Cal-Tech has attempted to model this by means of a series of transconductance amplifiers wired as simple delays with carefully-calibrated frequency "damping" per section.

My version models this with a simple R-C lowpass filter (integrator) and an op amp (buffer) per module. The first stage or module will have the highest cutoff frequency, approximately 5 KHz, and will set the resolution limit of the system. The output of the buffer, which reproduces the slightly low-pass filtered (and DELAYED) version of the original audio signal, goes on to the input of the next module.

The next module's R-C filter has a slightly lower cutoff frequency, say, 3 KHz. And so on, down to maybe 200 Hz. (Probably best to taper the cutoff frequencies LOGARITHMICALLY for economy and accuracy.)

Back to the first module, which had the highest cutoff frequency of the chain of modules we're building up... say, about 5KHz:

Across the series resistor forming part of our RC filter, we tap off two wires and run them into a comparator (op amp with no feedback resistor... = squaring amplifier). The input side of the resistor (before being low-pass filtered) goes to the (+) input of the comparator; the other lead of the resistor (which connects to the filter cap and then to the buffer input) goes to the (-) input of the comparator.

The comparator, therefore, constantly compares the two versions of the audio waveform at its terminals: the unfiltered/undelayed input vs. the filtered/delayed output side of the RC filter. When the input side is rising in amplitude, and exceeds the delayed output side, the comparator switches its output logic HIGH; when the input signal amplitude dips down below the delayed signal amplitude, the comparator switches LOW. THIS PRODUCES A VERY PRECISE "PEAK-CROSSING" DETECTOR WHICH TENDS TO SWITCH AT THE +/- PEAKS OF A SINE WAVE, rather than at the zero-crossings at the middle of the waveform.

Now we run this squared-off comparator output into a DIFFERENTIATOR --- a series cap (about .001uf) and a resistor to ground (10k) -- which hi-pass filters the square wave into sharp spikes having approximately a 10 uS time constant, nice and short. We have now generated a series of bipolar spikes whose position, relative to one another over time, is a function of the DIFFERENCE of amplitudes and phases of two slightly different copies of the original incoming sound wave.

A similar mechanism has been discovered within the retinal cells in the eye. Carver Mead has reproduced this one, too. I.e., a retina cell "computes" the [logarithm of the] DIFFERENCE between what it "sees" and what its immediate neighbors see -- and it tries to inhibit their outputs, producing automatic EDGE DETECTION which can be thought of as spatially high-pass filtering a visual scene; the result is that CHANGING brightnesses are emphasized. Play with a kitten and you'll notice a direct proportion between how fast you pull the yarn past its visual field and how badly the kitten feels it "has to" pounce on it. And frogs tend to ignore everything except quickly-moving black spots (flies) across its visual field.

This is likely the mechanism of neural coding by which we hear, also (or something like it). Living things tend to respond to CHANGES in sensory stimulus; long, monotonous stimuli lead to neural shutdown (boredom --> sleep) as any school teacher can tell you.

My version of Flanagan's Neurophone preserves several frequency-bands worth of harmonic information... but as time-domain spikes just as Flanagan says we need. And we don't hack the most interesting stuff off the top with this approach, like we do with simpler versions.

INTEGRATE, COMPARE, DIFFERENTIATE, and SUM -- A SUMMARY

Visualise the human cochlea as a long delay-line with damping (low-pass filtering) progressing as you go down the line. Picture a comparator every few millimeters, with its two inputs slightly separated, "sampling" across a small section of the delay line as the waves propagate down the line. An entire array of such comparators, with their outputs differentiated into10 uS spikes, perhaps "OR'd" together, would present a highly detailed PPM spike-train which, I predict, would produce an increased efficiency in frequency-to-time or analog-to-digital sound conversion for the next generation of homemade Neurophone-like devices.

HERE IS A QBASIC PROGRAM WHICH WILL RUN A SIMULATION OF THE ABOVE ON YOUR COMPUTER SCREEN.... drag your mouse across the following code, COPY it and SAVE AS a new file called COCHLEA1.BAS. Then, RUN it from your resident QBASIC environment.

The program generates a rippled, sawtooth-like "audio" waveform (white) made up of a fundamental and 10 harmonics, and then samples it several times, each time having a slightly lower cutoff frequency (longer time delay, more low-pass filtering). This is displayed in yellow.

The comparator output for each delay is plotted in green.

The superimposed differentiated spikes from all the comparators are plotted at the bottom of the screen in white.

Hope these ideas stimulate further research and development.

GAS FIRED CASELESS AMMUNITION RIFLE

This invention relates to a rifle designed to shoot caseless ammunition by charging the rifle with gas, and firing the charge electrically.

An object of the invention is to provide a rifle which will not jam after firing, because there is no empty cartridge shell or case to be ejected.

Another object of the invention is to gas charge, and electrically fire, a rifle in much the same manner as an internal combustion engine is operated. In this instance a projectile is substituted for the engine piston.

Another object of the invention is to provide a rifle which may be fired with hydrocarbons and oxygen, both in a gaseous state. This has various advantages over rifle using metal cases in that it is more economical to shoot and there is no need of buying expensive metal cased ammunition.

Another object of the invention is to provide a rifle which may quickly be adjusted to provide different amounts of foot pounds of muzzle energy, so that the same rifle can fire at long range, medium range, and for target practice with less wear and tear on the device and less fatigue to the operator.

Another object of the invention is to provide a device of the character indicated, which is provided with integrated receptacles for holding the gases which are to be mixed in the firing chamber.

Another object of the invention is to provide a device of the character indicated, which may be supported in the arms of the operator, or may be used as a light machine gun, in which event the gas tanks could be detached from the gun and carried separately.

Another object of the invention is to provide a device which may be mounted on a stationary member, or may be mounted on a mobile unit, or an airplane, with the tanks incorporated into the structure of the machine.

Another object of the invention is to provide a device of the character indicated, which fires clean and emits only CO_2 and H_2O.

Another object of the invention is to provide a rifle which may be fired electrically, or with caps, or with the compression of its own gases.

Another object of the invention is to provide a device of the character indicated, which is provided with a truncated cone insert in the firing chamber, which insert has comparatively thin walls which are contracted about the bolt by the exploding gases to prevent leakage of the gas around the bolt.

Another object of the invention is to provide a device of the character indicated, which may be manufactured and assembled inexpensively, in as much as it has few machined parts.

Another object of the invention is to provide a device of the character indicated, which will warm itself in cold weather and will facilitate its use under adverse weather conditions.

The foregoing and other objects and advantages of the invention will become more apparent as the description proceeds, reference being made from time to time to the accompanying drawing, forming part of the within disclosure, in which drawing:

FIG. 1 is a longitudinal, sectional view taken through a rifle embodying the invention.

FIG. 2 is an enlarged section taken substantially on the line 2—2 of FIG. 1.

FIG. 3 is a section taken substantially on the line 3—3 of FIG. 2.

FIG. 4 is an enlarged detail illustrating a typical wiring circuit when the device is fired electrically.

Referring now more particularly to the drawing, it will be understood that in the embodiment herein disclosed, the reference character **7** indicates the barrel of the rifle which has a breech block or receiver **8**, a bolt **9** having a handle **9A**, a stock **10**, hand grip **11**, trigger **12** and trigger guard **13**, all of which are conventional parts of a rifle and constitute no part of the invention except as they are combined with the elements hereinafter described.

The rifle embodying the invention is designed to shoot a bullet, or projectile **14**, which may be of any desired caliber and which is fed into the barrel **7**, by the bolt **9**, as in conventional, single action practice. The rifle may also be equipped to load the bullets automatically, although no claim is made to such mechanism in this application.

Instead of using a brass cartridge to carry the explosive charge, we intend to fire this rifle by means of a mixed charge of hydrocarbons gas (preferably butane) and compressed oxygen.

In the embodiment shown in FIG. **1** a compressed butane cylinder **15**, is housed in a suitable bore **16**, formed in the stock **10**. The cylinder **15** is provided with a shut off valve assembly **17** and a pressure regulator **18**. The cylinder **15** is connected to the firing chamber **19** through a passage way **20**, which passageway **20** is controlled by means of a valve assembly **21** and **22**, which is threadedly mounted on a lateral extension of the breech bolck **8** as at **23**. The valve member **21** is spring loaded as at **24**, and may be opened by striking the button **25** with the palm of a hand. The valve stem **21** has a head **26** which engages a seat **27** and when the head **26** is lifted from the seat **27**, the gas is permitted to enter the chamber **19** through the ports **28**.

A compressed oxygen cylinder **29** is supported by any suitable means **29A** and **29B**, under the barrel **7**. The oxygen cylinder **29** is provided with a shut off valve **30** and regulator mechanism **31** and communicates with the firing chamber **19** through a passageway **32** which is controlled by a valve assembly **33** and **34** having a palm button **35** similar to the mechanism **21–28** previously described in connection with the butane gas assembly.

Both the butane and oxygen being under compression, it is simply necessary to strike the buttons **25** and **35** to admit an explosive mixture into the firing chamber **19**. The explosive mixture in the firing chamber may be fired electrically, by means of a glow plug **36**, which is connected as at **37** to one side of a battery **38** (FIG. **4**), the other side of the battery **38** being connected as at **39** to a safety fuse **40**, which in turn is connected as at **41** to a contact element **42**, which is mounted on a lever **43**, which is part of the trigger mechanism **12**. The contact **42** is normally held away from the glow plug **36** by a spring **44**, which holds the trigger mechanism **12** in vertical position on the pivot **45** as shown in FIG. **4**.

The firing chamber **19** is provided with a frusto conical insert member **46**, which is threadedly received, as at **47**, in a suitable bore formed in the breech block **8**. The truncated cone member **46** has a central bore **48** in which is received a reduced portion of the bolt **9**. The member **46** is also provided with comparatively thin walls around the bolt **9**, as at **49**, so that upon the firing of the charge from the chamber **19** the back pressure of the explosive gases contract the walls of the member **46** tightly around the bolt **9**, to prevent escape of gases rearwardly from the chamber **19**. The member **46** is also provided with radial webs **50**, which trap the exploding gases and prevent them from swirling around the bolt **9** to more effectively exert pressure on the thin walls **49** to assist in sealing the firing chamber around the bolt area.

From the foregoing, it will be understood that by regulating the pressures in the passageways **20** and **32**, it will be possible to effect a greater or lesser explosive charge in the chamber **19**.

It is believed that the operation of the device is obvious from the foregoing description.

Having described our invention, what we claim and desire to secure by Letters Patent is:

1. In a rifle having a barrel, breech block, stock, hand grip and trigger assembly, the combination of a firing chamber in said breech block, means to seal said firing chamber against back pressure, means to feed caseless bullets to said barrel, a first compressed gas chamber, means to conduct gas from said first gas chamber to said firing chamber, a second compressed gas chamber in communication with said firing chamber, means to control the flow of gas from each of said gas chambers, and means to fire the mixture of gases in said firing chamber, to eject the bullets from said barrel, in which the means to seal said firing chamber include a truncated cone insert received therein, said cone having thin walls arranged to be compressed about the bullet feed means to seal the area around said feed means against gas leakage, upon firing the gas mixture in said firing chamber.

General George O. Squier

***Scientific American* (July 14, 1919, p. 624) ~**

"With Trees For Ears"

A Wireless Station Within the Reach of Everybody

With a pair of receives to his ears, an amazed visitor to a certain radio station heard a high-toned hum which changed to a low growl, then skied to the upper reaches of the musical scale in a

faint, very faint buzz, as if some microscopic mosquito had had his song made audible. The operator rapidly rapidly turning the knobs on his couplers and condensers, raised his hand: suddenly, through the changing radio signals which were clamoring for attention together in the receivers came his voice; "There --- the loud, easily heard one is New Brunswick; the fainter, lower one is Nauen, in Germany".

If all this had taken place in the great Arlington station one would not have wondered, save perhaps at the inability to tune out all radio but Nauen. But it was a little portable house erected in thick woods near the edge of the District of Columbia and the signals were received through an oak tree for an antenna.

It is not a joke nor a scientific curiosity, this strange discovery of Gen. George O. Squire, Chief Signal Officer, that trees --- all trees, of all kinds and all heights, growing anywhere --- are nature's own wireless towers and antenna combined. The matter first came to his attention in 1904, through the use of trees as grounds for Army buzzer and telegraph and telephone sets, which, in perfectly dry ground and in a dry season, functioned poorly or not at all with ordinary grounds. Right then he began experiments with a view to seeing what possibilities, if any, the tree had as an aerial. But in 1904 radiotelegraphy was far more undeveloped than at present, and vacuum amplifying tubes were not thought of.

During the war the Signal Corps established a chain of special receiving stations in different localities to copy and record enemy and allied radio messages. Some of those stations were instructed to test the efficiency of growing trees as receiving antennae.

With the remarkably sensitive amplifiers now available, it was not only possible to receive signals from all the principle European stations through a tree, but it has developed beyond a theory and to a fact that a tree is as good as any man-made aerial, regardless of the size or extent of the latter, and better in the respect that it brings to the operator's ears far less static interference.

This is a rather broad statement, yet there beyond the Capital of the nation stands a little portable house, the oak tree, a small receiving set and a couple of enlisted men and an officer on duty; and the curious may, with permission, hear for themselves that the signals so received are neither faint not interrupted, but strong, full-toned dots and sashes even when they come from far-off Nauen. Page after page is copied daily from the propaganda material which Nauen sends out by the ream. Lyons, Poldhu, ships at sea, even the NC-4 on her way, are heard plainly. As for New Brunswick or nearby Arlington --- they deafen the listener if he is unwise enough to try to "take" them otherwise than with the phones lying on the tables.

It will puzzle the amateur as it has puzzled the experts, how a tree, which is certainly well grounded, can also be an insulated aerial. The method of getting the disturbances in potential from treetop to instrument is so simple as to be almost laughable. One climbs a tree to two-thirds of its height, drives a nail a couple of inches into the tree, hangs a wire therefrom, and attaches the wire to the receiving apparatus as if it were a regular lead-in from a lofty copper or aluminum aerial. Apparently some of the etheric disturbances passing from treetop to ground through the tree are diverted through the wire --- and the thermionic tube most efficiently does the rest.

It is interesting to learn that the tree behaves very much like any other aerial; it receives better in dry clear weather than in muggy, damp weather. It plucks messages from the ether more clearly at night than in the day. It is affected very little by rain. It is affected not at all by the presence of other trees; so far as has yet been ascertained it makes little difference whether one drives his nail in a tree in the forest or a lone tree on the plain. Certainly it makes no difference that amounts to anything whether the tree be just an ordinary tree or a giant; it was a 60-foot oak over which the very awe-struck correspondent heard Nauen telling a waiting world what good people the Germans really are. And to prove that it made no particular difference what kind of tree was used the officer in charge switched to a pine tree, which received equally well.

A dead tree will not do, and a tree not in leaf is not so sensitive as one in full foliage. It makes much difference where the nail is driven. General Squier calls the proper place the optimum point, and experimentally it has been determined that two-thirds of the distance from ground to top is the best place -- in a 60-foot tree, 40 feet from the ground.

One nail is sufficient, and it may be any kind of nail; but copper is preferred as not rusting. In practice, if a tree station is to be at all permanent, several nails would be driven and connected to the same wire, each additional nail up to 6 or 8 making the diverted current a little stronger. But 40 nails apparently produce no clearer signals than half a dozen.

The tree may serve as a receiving station for several sets, either connected in series with the same material or from separate terminals.

Some skeptics have expressed the belief that it was not the tree, but the wire leading to the nail in the tree which was the real aerial. The absurdity of thinking a 40-foot wire could receive the widely differing wave lengths which come through the tree station is obvious, but to set any doubt at rest, the wire to the tree has been hung to the nail by means of an insulator, when the signals immediately cease, only to come in as strong as ever just as soon as the connection is again established.

Just what will the tree do as a transmitting station for radio telegraphic messages has not been determined in the Signal Corps Experimental Laboratory. As those in charge express it, "The fact has been demonstrated, but the matter is still in laboratory stage only. What remains to be done now is to develop the best methods of using the demonstrated fact".

But it has already been shown that the tree can be used in wireless telephony and for short distances it has been shown that two-way telephonic communications is easily established through trees with remarkably low values of transmitting antenna current.

If a tree may be used to send wireless telephonic waves it seems not unreasonable to suppose that it will do so as easily with the telegraphic waves. At present the Signal Corps is at work on apparatus to test the possibilities of the tree as a transmitting station.

Just what this development of the art of radio telegraphy may mean has not yet been worked out. It is the history of most discoveries that their potentialities are hardly dreamed of when they are first made --- for instance the telephone, the electromagnet, the vacuum tube amplifier. But it seems fairly obvious that in war, at least, the tree receiving station opens up great possibilities.

True enough there are few trees which remain intact under shell fire, and doubtless with this possibility in mind the armies of the future (if there be such) will in action consider all trees as dangerous enemy aerial stations. But there will always be trees behind the lines and not all actions will be fought on bare ground. What would it have meant to the "lost battalion" to have had a tree wireless set along by which it could have heard that every effort was being made to find and relieve it, or by which it might have sent back messages supplementing that carried by the pigeon?

The greatest development, however, of the tree as the foundation for a receiving and possibly a sending station will come in peace uses. General Squier has written:

"In view of what has been accomplished in space telegraphy, it is difficult to predict to what extent this means of communication may ultimately be developed. If, as indicated in these experiments, the earth's surface is already generously provided with efficient antennae, which we have but to utilize for such communication, even over short distances, it is a fascinating thought to dwell upon in connection with the future development of the transmission of intelligence.

"Since a transmitting station is a central point for electromagnetc waves sent out in all directions over the surface of the earth, a large class of information, such as meteorological reports, crop reports, and general news items of interest to all, may in time be sent from central points, to be received in many places within the radius of influence of the signal station, and this, too, by the simplest form of apparatus."

The amateur wireless world will unquestionably take an intense interest in the tree radio work. At present, while the government has lifted the ban upon amateur aerials, it has not removed the structures against sending.

The aerial is always the greatest problem for the amateur. Lack of both money and material prevents him from erecting anything very large or of very great capacity. If any lad with a receiving set and some thermionic tubes can hook to a tree and take in any wavelength he can tune to, will not tree radio vastly increase the devotees of this particular variety of indoor sport? The matter is one of some importance, inasmuch as many valuable recruits to the radio world have come from amateur ranks, and many a radio engineer had got his first taste for the fascinating art through a homemade tuning coil and detector, under the attic roof. The greater the amateur wireless world, the quicker the development of the art as a whole.

Explorers, discoverers, engineers in far places, the forest service, the woodsman, all have use for the new development. Moreover the tree as an antenna offers unusual possibilities for the investigation of atmospheric phenomena and for what may be called the physics of botany (or the botany of physics) and perhaps is the road by which the unsolved puzzle of growth may be studied.

Meanwhile, it is a thought not without great power to move the sensitive imagination that every tree, growing everywhere, is a wireless tower and antenna and that, as General Squier says, "It is significant that a tree, possessing utility and natural strength, architectural beauty of design and endurance far superior to artificial structures prepared by man, should be able yet further to minister to his needs".

Talking Through The Trees

by

Major-General George O. Squier

(Chief Signal Officer, US Army)

How Transatlantic Radio messages Are Copied Via Tree Antenna

As long ago as 1904, the author conducted some experiments with a view to utilizing growing trees as antennae for radio-telegraphy and discovered the efficacy, in a general way, of using a direct metallic contact to certain trees (principally Eucalyptus) to increase the audibility of radio signals. My attention was first called to this phenomenon during the course of summer maneuvers of the Army at Camp Atascadero, CA, where, due to the prevalence of the dry season of the soil, it was found that the regular Army buzzer telephone and telegraph sets were inoperative with any ordinary ground or earth but became operative when connected to a metallic nail driven in the trunk or roots of a live tree. This incident led the author to pursue the subject experimentally in the autumn of 1904 continuing the experiments to the range of frequencies than employed in radio-telegraphy.

Tree Antennae

In connection with the organization and development of Transatlantic radio reception, which was carried out during the period of the war to provide against the possibility of the interruption of the submarine cable system, the Signal Corps established a chain of special receiving stations in different parts of the United States to copy and record enemy and Allied radio messages from European stations for the information of our Army General Staff.

In the prosecution of this work, directions were given to the Signal Corps Laboratory at Camp Alfred Vail, Little Silver, NJ, and also to the experimental staff in Washington to test the efficiency of growing trees as receiving antenna, in connection with this service, using the vastly superior technique and facilities now represented in the radio Art as compared with the crude apparatus with which the discovery was made in 1904. With a collection of apparatus representing the most advanced state of the radio Art, the problem, as a war measure, was attacked anew and has now reached a point where a very brief outline of some of the physical results obtained should be presented in the interests of the development of the Art in general. Since the phenomena involved embrace a variety of physical problems rather than strictly engineering ones, these data are presented in the hope that our scientists may see in the experiments some points of departure for further research.

It was immediately discovered that with the sensitive amplifiers now in use it was possible to receive signals from the principal European stations by simply laying a small wire netting on the ground beneath the tree and connecting an insulated wire to a nail driven in the tree well within the outline of the tree top. See Figure 1. Messages having been received from England, France, Germany and Italy.

This encouraging first result justified a more careful examination of the phenomena and the most suitable arrangement of circuits for the purpose.

And Now For the Floraphone

The messages carried over this tree telephone and telegram system have been named by the writer. They are to be ‘floragrams’. The tree telephone is to be a ‘floraphone’; the tree telegraph a ‘floragraph’.

The discovery is now announced after experiments covering 15 years, beginning in California and continuing intermittently until the outbreak of the war, when they went forward with vigor as an emergency means of communication. The system was utilized during the war in listening-in on the German radio communication.

The final development took place in a small portable laboratory, purchased from a mail order house, capable of being carried to any place in the woods. A group of soldiers, taking turns at copying messages, assisted the writer in the development of the apparatus.

Without entering into the details of these preliminary experiments here it may be said that one fo the best receiving arrangements is found to be an elevated tree earth-terminal in the upper part of the tree top, and an earth consisting practically of several short pieces of insulated wire, sealed at the outer end, radiating out from a common center, and buried a few inches beneath the surface of the ground in the neighborhood of the tree. See Figure 2.

It was soon found that a tree-antenna could be used efficiently as a multiple radio receiving set over widely different wavelengths, see Figure 3A, receiving either from separate terminals at the same (shown dotted in Figure 3A) or different heights of the tree, or in series from the same terminal. See Figure 3B.

This same type of circuit was employed in an inverse manner for radio-telephonic transmitting purposes, although the experiments thus far have been limited to short distances. It was found that 2-way radio-telephonic communication was easily established with remarkably low values of transmitting antenna current. See diagram of this test illustrated at Figure 4.

The flexibility of this arrangement is very striking. The linking up of wire and wireless methods was found to be both convenient and efficient. Radio-telephonic messages from airplanes were readily received by the tree-antenna arrangement and transferred thence to the wire system of the city of Washington and finally received at any point desired.

Furthermore, radio-telephonic transmission through the tree-antenna was received by another tree-antenna, and automatically returned to the sender on a wire system, thus making a complete circuit. Illustrated at Figure 6.

Long distance reception on any wave length from all the larger European stations and from our ships at sea was easily accomplished and traffic copied on a 24 hour schedule by the regular enlisted operators of the Signal Corps. A small portable house serving as a field laboratory was erected in the midst of the forest area on Grant Road, Washington DC, and here was assembled a collection of amplifiers from the Army, navy, the British and French, and American manufacturers. With these facilities it was a matter of a few days to test out, at least in a superficial manner, a large number of proposed arrangements using trees as antenna.

Figure 7 shows how a number of trees can be connected up to give the effect of one large antenna.

In France officers of the Signal Corps, by the simple device of driving a spike into a tree-trunk to which connect the audion set which wireless operators use to make up wireless messages, it was found possible to listen in on communications between German airplanes and the German lines. Messages were thus intercepted in spots into which it would have been impossible to transport a field wireless apparatus. See Figure 8.

The Physics of Tree Wireless

We may regard the metallic electrode rigidly driven into the living organism of a tree, as described above, as a potential earth-terminal for the study of the potential distribution on the surface of the earth itself. It has been shown in these experiments that this metallic terminal intimately connected to the earth itself and a part thereof is subject to changes of potential representing the innumerable frequencies required by modern radio-telephony and telegraphy, as well as any other electrical disturbances which may occur on the surface of the earth or the atmosphere above the earth.

It has also been shown, as expected, that we can select from this composite one or more of the different frequencies by tuned electrical loop circuits suitably connected to this electrode and study each in turn, at will, just as color screens can select a particular component of white light. We may, indeed, by means of a highly insulated conductor bring this terminal directly to the laboratory and connect it immediately to the modern thermionic tube and amplify almost at will the particular effects we are studying…

We can consider that trees have been pieces of electrical apparatus from their beginning and with their manifold chains of living cells are absorbers, conductors and radiators of the long electromagnetic waves as used in the radio Art.

For our present purpose we may consider, therefore, a growing tree as a higly organized piece of living earth, to be used in the same manner as we now use the earth as a universal conductor for telephony and telegraphy and other electrical purposes…

British Patent Specification # 149,917

Improvements in & Relating to Radio Communication Systems

George O. Squier

This invention relates to radio communication systems. More particularly, the invention relates to radio transmission and reception through the use of living vegetable organisms such as trees, plants, and the like.

As disclosed in the Specification of my prior Letters Patent No. 25,610 (1904), I have discovered heretofore that tall trees and like growing vegetation possessed electrical conductivity of a certain nature adapted for the reception of signaling electromagnetic waves and capable of forming a part of an antenna or serial with the use of a direct earth "ground" or equivalent point of connection with the tree, in the potential node region.

I have recently discovered that living vegetable organisms generally are adapted for transmission and reception of radio or high frequency oscillations, whether damped or undamped, with the use of a suitable counterpoise. I have further discovered that such living organisms are adapted for respectively transmitting or receiving a plurality of separate trains of radio or high frequency oscillations simultaneously, in the communication of either or both telephonic or telegraphic messages.

In such use of an antenna comprising living vegetable organism and a counterpoise, I have discovered that optimum results are obtained upon arranging the point of connection of the transmitting or the receiving set within a certain range of the tree, or other living vegetable organism; for trees indigenous in the temperate zones, I have discovered that such optimum point of connection is in a region approximately two-thirds of the height of the tree above the exposed surface of the earth.

In accordance with my invention for receiving radio trains of telephonic or telegraphic high frequency oscillations, a plurality of receiving sets attuned respectively to any desired frequency, may be connected by the same leading-in wire to the same tree, whereby such tree serves as the common receiving antenna for the respective individual receiving sets; and, similarly, for transmitting radio trains of telephonic or telegraphic high frequency oscillations, a plurality of transmitting sets respectively resonant to any desired frequency may be connected by a common lead-in wire to the same tree serving as the common antenna.

In the more preferred forms of my invention, I have devised suitable means for selective directional reception of radio oscillations of any desired definite frequency, by the use of a coil having the turns of its windings disposed in substantial parallelism and mounted to be rotated in a horizontal plane, whereby the received oscillations are restricted to the direction coincident with or parallel to a plane lying normal to any plane passing through any turn of the windings of the coil.

The counterpoise comprises preferably a suitable extent of conductor in the form of one or more lengths of wire disposed below the surface of the earth and suitable insulated therefrom; it is desirable to arrange a number of individual counterpoises, each extending rectilinearly in different directions to one another and to employ in directional selection the particular counterpoise extending substantially in the selected direction.

Further features and objects of the invention will be more fully understood from the following description and the accompanying drawings, in which:

Figure 3 is a diagrammatic view of a preferred form of an arrangement of transmission sets embodying my invention.

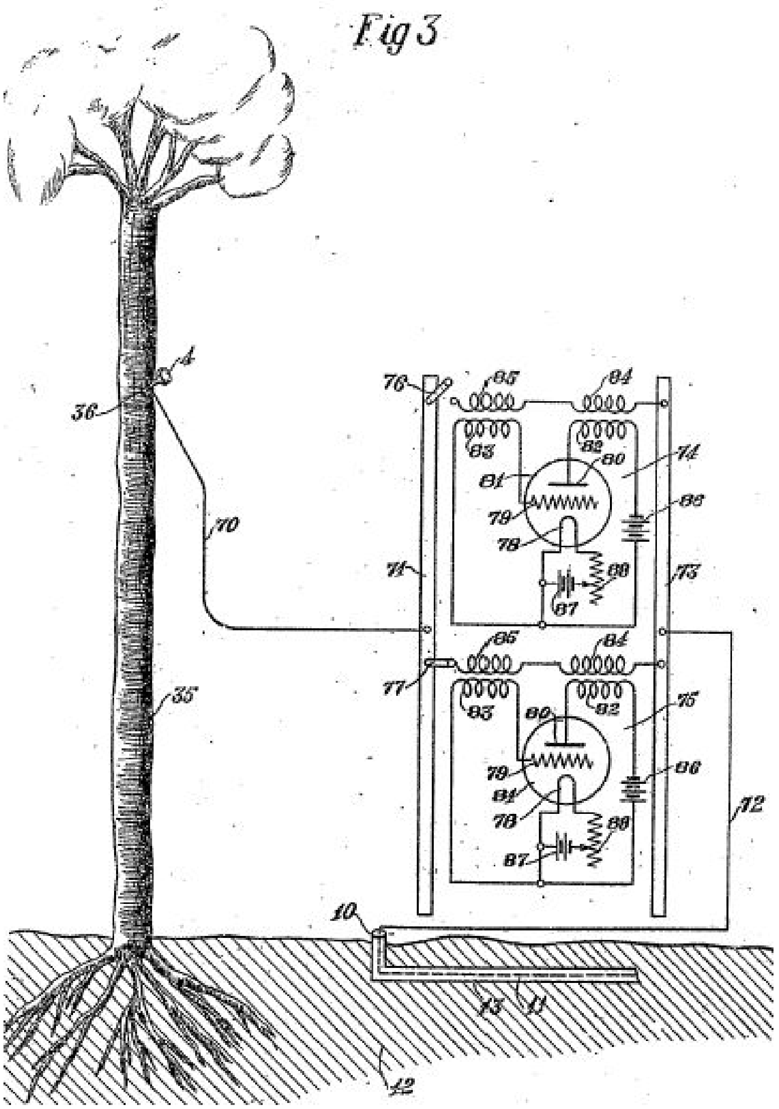

Fig 3

Referring to Figure 1, the circuit designated 1 represents any approved form of resonant receiving circuit comprising the variable condenser 2, and detector, rectifier or amplifier 3, arranged with a telephone or any suitable recording device in the usual manner. Such attuned receiving circuit 1 is suitably coupled through transformer windings or otherwise with proper regulatable reactance with the tree or other living vegetable organism and in Figure 1 I have indicated the location 4 as representing the location of a metallic nail, or equivalent, affixed to and extending within the body of such tree. I have discovered that optimum results for any particular tree are dependent upon the physical contour of the space occupied by the branches and leaves as well as the subterranean portions of the tree such as the roots and that generally the optimum results are attained by affixing the nail 4 within the region of the tree substantially two-thirds of the height of the tree above the surface of the earth.

To such nail 4 is connected one end of the lead-in wire 5, preferably enclosed in suitable insulation, and connected at its other end with the resonant circuit 6 comprising the adjustable inductance coil 7 and the adjustable condenser 8. The lead 9 connects the circuit 6 with the counterpoise 10, preferably comprising one or more metallic wires, 11, extending substantially rectilinearly and electrically insulated from the earth 12 by means of suitable insulation 13, as by enclosing such wire or wires 11 within a suitable insulating coating. Such coating 13 extends preferably an appreciable distance above the surface 14 of the earth 12. In the use of my invention with living antennae, I have arranged the counterpoise 10-13 extending in the rectilinear direction substantially parallel to the plane passing through the transmitting station, the receiving station and the center of the earth. It is advantageous to arrange a plurality of individual counterpoises 10 radiating in different rectilinear directions, with a suitable switching device for connecting the lead 9 with the particular counterpoise parallel to or most closely parallel to the selected direction.

Such coil 7 is preferably a primary coil suitably spacially coupled with an adjustable secondary coil 15 connected in the circuit comprising the variable condenser 2 and 3. In the specific form of the invention shown in Figure 1, such secondary coil 15 is provided with the lead wire 16 connected to the terminal 17 of the reversing switch 18 (shown diagrammatically) the other end of the secondary coil 15 being connected by the cross wire 20 of the reversing switch 18. Such terminal 17 is connected by the cross wire 21 with the terminal 24. The pivoted knife blades 25, 26, having the handle 27, are mounted in the usual manner on the central terminals 28, 29. The coil 30 represents diagrammatically a coil comprising a desired number of windings or successive turns of exposed or insulation covered wire, each turn lying substantially in a common vertical plane and the coil indicated at 31 represents a similar plurality of turns of windings mounted in substantially a common vertical plane. One terminal of the coil 30 is connected with one of the central terminals of the reversing switch 18, say terminal 28, and one terminal of the coil 31 is connected with the other central terminal 29, of the reversing switch 18. The other terminal of the coil 30 is connected by the wire 32 with the leads of the variable condenser 2 in shunt with the detector or amplifier 3, while the other terminal of the coil 31 is connected by the wire 33 to the opposite lead of the variable condenser 2 and the detector or amplifier 3.

Such set of coils 30, 31 are suitably mounted to be rotated horizontally, whereby all turns of the coils 30, 31, at any given position lie substantially in a common vertical plane. Such coils 30, 31 may be arranged on a common wooden or like insulating frame of cylindrical, rectangular or other desired contour on cross section.

By virtue of such an arrangement, the primary and secondary circuits are respectively directly exposed to and simultaneously electromagnetically acted upon by the incoming oscillations, and by means of the reversing switch 18 the oscillations generated in the coil 30 may be neutralized or accumulated relatively to the oscillation generated in the coil 31 to produce either the "barrage" or the "amplifying" effect.

By means of such "barrage" effect, the oscillations of any given wavelength directed in any absolute direction are cut out from the detector or amplifying circuit and enable oscillations of similar or the same wave length received in any definite direction to be conducted to the detector or amplifying circuit. By means of such accumulating effect of the coils 30, 31, and the switch 18, the waves of any definite wavelength received in any definite absolute direction are amplified and enable long distance reception at any wave length.

In practice, I have carried out the invention for reception by the use of either a single receiving set or a plurality of receiving sets. Such receiving set or sets may be arranged either to receive damped high frequency oscillations or undamped high frequency oscillations.

In Figure 2 I have illustrated diagrammatically one form of the application of the invention for the simultaneous reception of a plurality of different trains of high frequency oscillations.

The nail 4 is indicated as located in electrical connection with the tree 35 at an optimum point 36, the lead-in wire 37 being connected at its upper end with the nail 4 and at its lower end with the incoming connector bar 38. The connector 38 is provided with the individual switches 39-40-41, etc., corresponding to the number of individual receiving sets. The outgoing connector bar 42 is connected by the lead 43 with the counterpoise 10, preferably constructed and arranged as set forth hereinabove.

In suitable relation with the incoming connector bar 38 and outgoing connector bar 42 and the switches 39, 40, 41 are arranged the respective primary coils 44, 45, 46, etc., respectively coupled in any approved arrangement with the secondary coils 47, 48, 49.

The receiving set 50 is arranged for the reception of undamped waves and is shown of the vacuum tube valve type. The terminals of the secondary 47 are suitably connected in the input circuit including the filament cathode 51 of the vacuum valve 52 and the grid 53 and comprises the variable condenser 54 in shunt with the secondary 47, the condenser 55 and the grid leak resistance 56. The output circuit comprises the battery 58, the filament cathode 51, and the telephone receiver or other audible, or any visual indicator 57. The heating circuit of the filament cathode includes the battery 60 and the variable resistance 61.

The receiving set 62 is shown of a similar undamped oscillation receiving type and like elements are designated by like reference numbers.

The receiving set 63 is indicated of the damped oscillation receiving type and comprises the additional inductance turns 64 having one terminal connected to one terminal of the filament cathode 51 and its other terminal connected to the variable condenser 65 in shunt with the telephone receiver 57 and the storage battery 58. The remaining elements of the receiving set 63 correspond to like elements of the receiving set 50 and are designated by like reference numbers.

In Figure 2 I have shown the switch 39 in closed position with the primary inductance 44 of the receiving set 50, the switch 40 in closed position with the primary inductance 45 of the receiving set 63 and the switch 41 in open position with the primary inductance 46 of the receiving set 62, and accordingly enabling the reception and detection of undamped oscillations of the frequency to which the receiving set 50 is tuned and simultaneously the reception and detection of damped oscillations of the frequency to which the receiving set 53 is tuned.

Figure 3 shows one form of practical application of my invention for transmitting simultaneously radio oscillations, either telephonic or telegraphic, either damped or undamped, or both. The nail 4, lodged at an optimum point 36 in the tree 35, is connected by the lead 70 to the connector bar 71, and the counterpoise 10 is connected by the lead 72 to the connector bar 73.

The transmitting sets 74, 75, etc., of the desired number, are suitably arranged for single or multiple transmission, for which purpose the switches 76, 77, etc., are provided. The transmitting sets 74, 75 are shown of any approved type, such as the oscillating vacuum tube type comprising the filament cathode 78, the grid 79 and anode 80, arranged in the vacuum tube 81, suitably connected with the primary inductance 84, 85. The primary inductances 84, 85 are suitably connected to the connector bar 73 and the connector bar 71 through the respective switches 76, 77. The battery or other source of electric current is indicated at 86. The adjustable heating circuit of the cathode filament 79 is shown comprising the battery 87 and the variable resistance 88.

In Figure 3, the switch 77 is in closed position thus placing the transmitting set 75 in operative connection with the tree serving as the antenna. Upon closing the switch 76 the transmitting set 74 is similarly placed in operative connection with the tree antenna 35. Upon closure of both switches 76, 77 the tree serves as the antenna for the transmission of simultaneous trains of oscillations emitted by the respective transmitting sets 74, 75, modified by a key or telephone transmitter, or other suitable modulator, for the transmission of telegraphic or telephonic messages as desired.

In the use of trees or other living vegetable organisms serving as the antenna or a art thereof, I have discovered from tests that such tree possess impedance consisting of two components, resistance and reactance, the latter being usually condensive, for oscillation within the range of present day wavelengths. The tests also show that the apparent capacity of a tree serving as an antenna is substantially proportional to the height of contact of the lead wire connecting the transmission set with the tree.

The tests also show that the apparent resistance of a tree serving as an antenna is appreciably greater than the resistance of the ordinary metallic antenna, and it is accordingly desirable to modify the resistance or alter the design of the receivers, if it desired to increase the effectiveness of the energy of the electromagnetic radiation impinging on the tree; however, the ordinary receivers of present design may be used and are responsive to any wave length of radiation employed in present day practice.

Whereas I have described my invention by reference to specific forms thereof, it will be understood that many changes and modifications may be made without departing from the spirit of the invention as defined by the appended claims.

An alternative electric power generating system that draws energy from a seemingly unlikely yet abundant, eminently renewable and virtually free power source has been submitted for patenting by MagCap Engineering, LLC, Canton, Mass., in collaboration with Gordon W. Wadle, an inventor from Thomson, Ill. Wadle has invented a way to capture the energy generated by a living non- animal organism --- such as a tree.

Source: KeelyNet / Jerry Decker email (12/21/05)

"Unlimited Electric Energy from the Environment?"

Chris Lagadinos, president of MagCap, developed circuitry that converts this natural energy source into useable DC power capable of sustaining a continuous current to charge and maintain a battery at full charge.

"As unbelievable as it sounds, we've been able to demonstrate the feasibility of generating electricity in this manner," said Wadle.

"While the development is in its infancy, it has the potential to provide an unlimited supply of constant, clean energy without relying on fossil fuels, a power generating plant complex or an elaborate transmission network."

Wadle likened the invention to the discovery of electricity over 200 years ago when charged particles were harnessed to create an electric current. "Now we've learned that there is an immense, inexhaustible source of energy literally all around us that can be harnessed and converted into usable electric power," he said. Ultimately, it should prove to be more practical than solar energy or wind power, and certainly more affordable than fuel cells, he added.

Wadle said he got the original idea of harnessing a tree for electrical energy from studying lightening, more than 50 percent of which originates from the ground. This prompted him to develop the theories resulting in a method to access this power source.

Lagadinos then designed circuitry that filtered and amplified these energy emanations, creating a useable power source.

Basically, the existing system includes a metal rod embedded in the tree, a grounding rod driven into the ground, and the connecting circuitry, which filters and boosts the power output sufficient to charge a battery.

In its current experimental configuration, the demonstration system produces 2.1 volts, enough to continuously maintain a full charge in a nickel cadmium battery attached to an LED light. "Think of the environment as a battery, in this case," said Lagadinos, "with the tree as the positive pole and the grounding rod as the negative."

Lagadinos said the system could be enhanced enough to generate 12 volts and one amp of power, "a desirable power level that could be used to power just about anything," he said. It is enough power to charge batteries for any type of vehicle, including hybrids and electric cars, or to use with an AC converter to produce household power, he added. The LED industry is a prime example of a potential user of this power source.

While the basic concept of this invention -- using a tree to generate electric power -- seems too incredible to be true, Lagadinos said it can be demonstrated quite simply. "Simply drive an aluminum roofing nail through the bark and into the wood of a tree -- any tree -- approximately one half inch; drive a copper water pipe six or seven inches into the ground, then get a standard off-the-shelf digital volt meter and attach one probe to the pipe, the other to the nail and you'll get a reading of anywhere from 0.8 to 1.2 volts of DC power," he said.

"You can't do anything with it in that form because it is 'dirty' -- i.e. highly unstable and too weak to power anything," he added. In order to properly harness this potential energy source, MagCap devised two test circuits: one with three capacitors that were connected in parallel by means of a switch and charged to 0.7 volts each.

When fully charged they are switched to a series mode, multiplying the voltage to 2.1 volts and flashing an LED to show that sufficient power could be generated to produce a useable result. The second circuit included a filtering device to stabilize and "clean" the current so it could be used to charge and maintain a NiCad battery.

The battery then could be connected to the LED to keep the LED lit continuously. Wadle pointed out that there seems to be no limit to the amount of power that can be drawn from an individual tree, no matter how many "taps" are inserted -- each produces the same amount of energy, an average of 0.7 - 0.8 volts. Size of the tree also seems not to matter.

Interestingly, while conventional wisdom would seem to indicate that the tree draws much of its energy from photosynthesis via its leaves, the voltage output actually increases to 1.2-1.3 volts in the winter after the leaves have fallen.

Outline

1. Vertical current flow and the global circuit
2. Findings supporting the global circuit
3. Measurements of global circuit parameters
4. Variability in the global circuit
5. Applications and planetary global circuits

Atmospheric electricity

Atmospheric electricity is concerned with:

•electrical properties of the lower and upper atmosphere
•currents flowing in the **fair weather atmosphere**
•**ionisation** of atmospheric air by natural radioactivity and cosmic rays
•**charging of particles** and droplets, snow and hail
•**charges** separated by thunderstorms and disturbed weather
•**currents** flowing from thunderstorms
•**Electric fields** in thunderstorms, the upper atmosphere and the fair weather atmosphere
•initiation of **lightning**

0. Historical background and some key individuals

Benjamin Franklin (1706-1790) – *Statesman, a Founding Father of the US, and scientist*

Giambatista Beccaria (1716-1781) – *Professor of Experimental Physics, University of Turin*

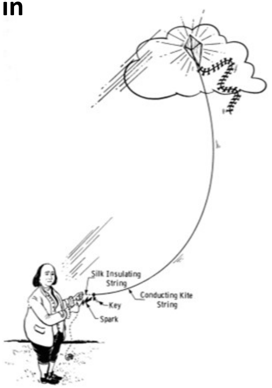
Lord Kelvin (1824-1907) - *Experimental and mathematical physicist, University of Glasgow*

Victor Hess (1883-1964) – Austrian physicist, discoverer of cosmic rays (Nobel Prize 1936)

CTR Wilson (1869-1959) – Scottish physicist, inventor of the cloud chamber (Nobel Prize 1927)

Sir Edward Appelton (1892-1965) – English physicist and discoverer of the ionosphere (Nobel Prize, 1946)

1750s - Benjamin Franklin

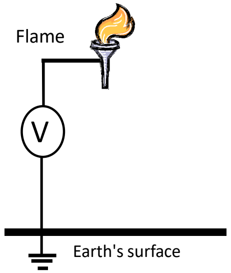


M.A. Uman, All about lightning, Dover, 1986

but.. debatable whether *he* actually conducted this experiment…

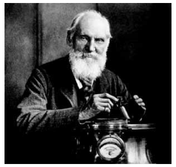
Scientific motivation: the origin of the "fair weather" field

Key finding: measurements by Lemonnier, Canton and others in 1750s detected positive electrification in fair (or "serene") weather conditions



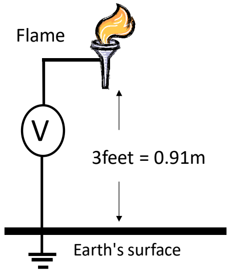
→ *Why, in fair weather (no thunderstorms present), using a flame probe sensor, does the voltmeter record a positive voltage?*

Lord Kelvin's standardised measurements



"The height of the match was 3 feet above the ground, and the observer at the electrometer lay on the ground to render the electrical influence of his own body on the match insensible. The result showed a difference of potentials between the earth (negative) and the air (positive) at the match equal to that of 115 elements of Daniel's battery."

29th meeting, British Association for the Advancement of Science, Aberdeen, September 1859



1 Daniel Cell (Zn/Cu) generates 1.08V

→ 115 Daniel cells = 124.2V

(vertical) **Potential Gradient**

Aberdeen (8am, 14th September, 1859)

= 124.2V / 0.91m = 137 Vm^{-1}

Kelvin’s interest in the variability

> *“There can be no doubt but the electric indications, when sufficiently studied, will be found important additions to our means for prognosticating the weather …[I] hope to soon see the atmospheric electrometer generally adopted as a useful and convenient weather-glass” (Lord Kelvin, 18th May 1860)*

Thomson, W. Reprint of papers on Electrostatics and Magnetism Macmillan, London, 1872

The variability which he observed probably challenged Kelvin’s world view, which may be the reason he sought to devise methods to investigate it – he was also central in developing telegraphy technology, which might have been affected by atmospheric disturbances

See: K.L. Aplin and R.G. Harrison, Lord Kelvin's atmospheric electricity measurements *History of Geo- and Space Sciences* **4**, 83-95, 2013 doi:10.5194/hgss-4-83-2013

Paradigm shift around 1900

- Kelvin and others’ understanding of atmospheric electricity was based on an electrostatic view, perhaps informed by the Victorian view of an “inherited” earth system
- But…work on ionisation and current flow by C.T.R.Wilson (and, independently, by Elster and Geitel in Germany) led to the electrostatic viewpoint becoming untenable
- Evidence indicating continuing atmospheric current flow brought with it the concept of a varying, dynamic, terrestrial atmospheric electricity system

K.L. Aplin and R.G. Harrison, Lord Kelvin's atmospheric electricity measurements *History of Geo- and Space Sciences* **4**, 83-95, 2013 doi:10.5194/hgss-4-83-2013

1. Vertical current flow in the fair weather atmosphere

Measuring vertical current flow

Charles Thomas Rees "CTR" Wilson (1869-1959)

- **Nobel prize winner (1927) for invention of the cloud chamber**
- **also demonstrated ionisation in air (*c*1900), which implied atmospheric charge was continuously replenished through current flow**

"I remember the satisfaction I had when my work led to the fulfilment of my dream of isolating a portion of the earth's surface and measuring the charge upon it and the current flowing into it from the atmosphere."

Wilson C.T.R., 1960. Reminiscences of my early years. *Notes & Recollects Royal Society* 14, 2, 163-173

$= 62$

"Three lightning discharges upwards per square km per year of 20 coulombs would be sufficient.

It is not impossible that even in Cambridge there may be that number of lightning strokes per square km per year."

(B8)

Electrical conductivity of air, σ

Air is not a perfect insulator – it is weakly conducting due to presence of ions

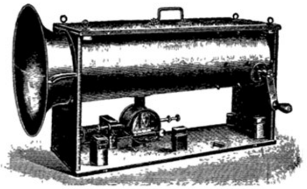
Electrical conductivity describes ability of air to conduct electric current

Coulomb discovered this property in 1785– he noticed that charge on an object decayed slowly with time

Subsequent work by Elster and Geitel 1900, and Gerdien 1905 developed instrumentation for balloons to further characterise atmospheric ions and measure conductivity

Conductivity inferred from rate of decay of charge on electrode

=> Measurement principles still used today



Balloon-borne conductivity apparatus from Gerdien (1905)

Ionisation measurements

Early 1900s, observations showed that charge decay occurred inside electroscopes (charge measuring devices working by mechanical deflection) that were well insulated from outside (Wilson, Elster and Geitel)

What was the source of ionisation?

Ionisation due to natural radioactivity was one source – originated at ground level, therefore ionisation should decrease with height

Balloon measurements during (1911-1913) by Victor Hess showed that ionisation decreased with height for first few hundred meters, then increased

Measurements during a solar eclipse showed that the sun was not the origin of the radiation

=> Discovery of galactic cosmic rays – the lower atmosphere's principal ionising agents

Vertical profile of air conductivity

Electrical conductivity of air results from the small ions it contains, generated by natural ion production from radioactivity and cosmic rays

$$\boxed{\sigma = 2\, n\, \mu\, e}$$

σ =total conductivity

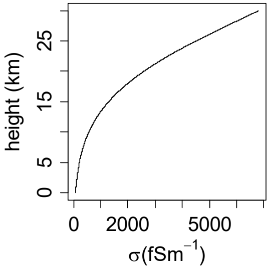
n = ion number concentration

μ = ion mobility

e = electronic charge

Typically $\sigma \sim 10^{-14}\ \Omega^{-1}\ m^{-1}$ in surface atmospheric air, or using SI ~ 10 fS m^{-1}

Only **small** ions (d ~1nm) contribute to σ



Ion production rate varies with height (decreasing terrestrial ionisation but increasing cosmic ionisation)

Ion mobility also varies with temperature and pressure

→ Conductivity profile

Columnar resistance, R_c

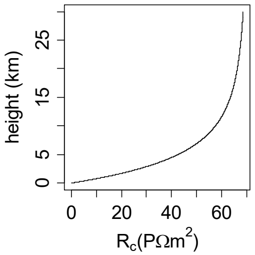
•Columnar resistance is the found from the reciprocal of conductivity σ(z)

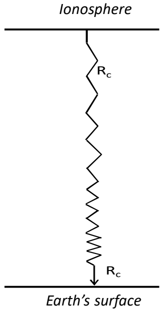
•Expressed as an integrated resistance, of a unit area column of air:

$$\boxed{R_c = \int_0^{z_I} \frac{dz}{\sigma(z)}}$$

•z = altitude
•z_I = height of upper conducting layer

•R_c~ 50 to 300 PΩ m²



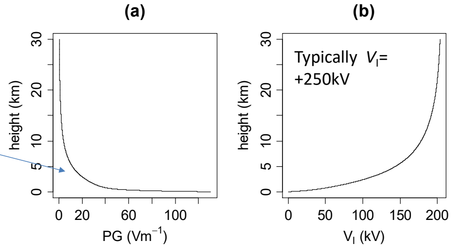


•most of R_c contribution is from lowest few km of atmosphere

Ionospheric potential - V_I

•The potential increases with height, to a maximum value essentially constant from the stratosphere to the ionosphere – known as the **ionospheric potential** V_I

•V_I is found from integrating the vertical profile of PG, measured by radiosonde balloons or aircraft, carrying a field mill or radioactive collectors. It is essentially a **global equipotential**



most variation in potential is within the lowest 10km

Typically V_I= +250kV

If the PG at height z is written as $F(z)$

$$V_I = \int_0^{z_I} F(z)\, dz$$

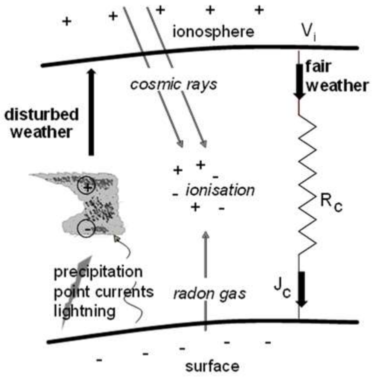
Local to global - Wilson's "global circuit" conceptual model

Wilson's "global atmospheric electric circuit", describes electrical characteristics of the atmosphere:

Source: ***Thunderstorms and rain clouds*** *transfer positive charge to the ionosphere in disturbed weather regions*

Sink: *In fair weather regions the air-earth current density J_c returns a small "conduction current" to Earth .*

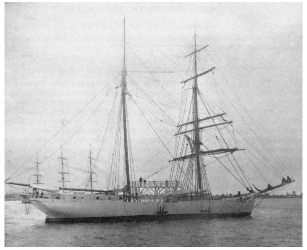
- Atmosphere bounded by upper and lower "conducting" layers
- Global thunderstorms and rain clouds charge upper layer to ~ + 300kV (V_i)
- Vertical current density J_c (~ 2pAm^{-2}) of cluster ions flows in fair weather regions
- Unit area "Columnar resistance" R_c ~ 150PΩm^2



2. Findings supporting the global circuit concept

Ocean measurements: the *Galilee* and *Carnegie*

The *Galilee* and *Carnegie* were the Carnegie Institution of Washington's geophysical survey ships. The *Galilee* was ultimately unsuitable as some magnetic parts could not be replaced; the *Carnegie* was a replacement constructed specially, built from wood, copper and bronze, with an observing deck



Galilee – brigantine built in 1891, as a fast packet between San Francisco and Tahiti. Chartered by CIW in 1905.

Carnegie under full sail in 1909 at launch. From 1909 to 1929 she covered 500,000km, and made the fastest circumnavigation of Antarctica.

Difficulties with early instrumentation

- Atmospheric electricity development work was delayed, until the final cruise of the *Galilee.*
- These first measurement attempts proved very difficult. In particular, the atmospheric electric field (Potential Gradient, PG) measurements…

> *"…seemed quite impracticable…the rolling of the ship, the flapping of the sails, and the varying position of the yards and boom under various sailing conditions all contributed to make the problem of reducing observations of potential-gradient to a uniform basis too complicated…"* [CIW175v3, p364]

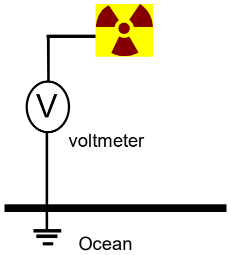
- Of several atmospheric electricity instruments considered for the *Galilee* (e.g. the Ebert ion counter) only air conductivity measurements, using a Gerdien aspirated device, showed practical promise.
- Air ion measurements were made on cruise I of the *Carnegie* (1909-1910), alongside observations of "specific conductivity" and "radioactive content".

Ion content of the atmosphere, 1911 (CIW)

R.G. Harrison, The Carnegie Curve *Surv Geophys* **34**, 2, 209-232, DOI: 10.1007/s10712-012-9210-2 (2013)

Potential Gradient sensors

Principle: radioactive "collector" methods to acquire local potential



Carnegie cruise 2 (1910-1913)
Kidson and Johnston used two radium collectors suspended on a bamboo pole, extending aft from the stern rail; Hewlett tried ionium (^{232}Th) collectors

Carnegie cruise 3 (June 8th 1914 to Oct 21st 1914)
PG used ionium collectors suspended on a bamboo pole, extending aft from the stern taffrail; standardization achieved by simultaneous ship and shore observation on two occasions, at Reykjavik and Gardiners Bay: average PG for whole cruise 93 Vm^{-1}

Carnegie cruise 4 (1915-1916)
special "atmospheric-electric" house built aboard to reduce set up time, and keep instruments in stable conditions, but the ionium coated collector plate on bamboo pole took too long (~2min) to come within 1V of the final steady potential

Mechanical Potential Gradient sensor

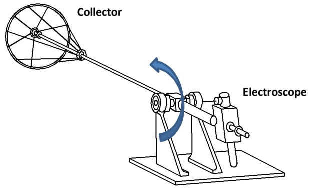
A new faster electric field measurement method was developed, which also compensated for tilt of ship

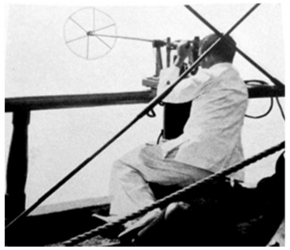
-a "parasol" collector was constructed from gauze on a pivot arm, to allow it to be adjusted for ship angle.

-Rotated from an earthed (pointing downwards) position, to horizontal to horizon, and **change in electroscope** reading recorded. (Hourly data)

-sustained good quality insulation was not needed; used sulphur insulators. The handle's hard rubber insulation was more critical, and had to be kept clean. Daily leakage tests

-battery offset for electroscope could also be applied





R.G. Harrison, The Carnegie Curve *Surv Geophys* **34**, 2, 209-232, DOI: 10.1007/s10712-012-9210-2 (2013)

Diurnal cycle results from Cruises 4, 5 and 6

By 1921, using harmonic analysis on the previous decade's data, the principal contributor to the PG's diurnal variation was a 24 hour component, and it was reported by its discoverer, the Carnegie Institution's S.J. Mauchly, that

> *"…the 24 hour Fourier wave was at the great majority of land stations in practical phase agreement on **universal time** with the prime daily wave over the oceans without regard to location.* [CIW175v5,p387]

This indicated that the origin of the potential gradient was not local

Mauchly SJ, Note on the diurnal variation of the atmospheric electric potential gradient *Phys Rev* n.s. **18**, 161-162 (1921); Mauchly SJ, On the diurnal variation of the potential gradient of atmospheric electricity *Terr Mag* **28**, 61-81 (1923)

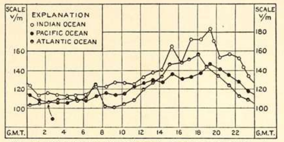


Fig. 24.—Mean Value of the Potential Gradient for the Different Oceans from Observations on the *Carnegie*, 1915–1921.

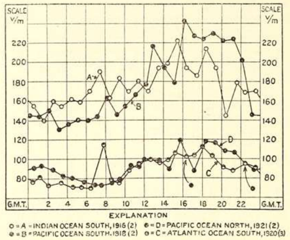

Fig. 25.—Comparison of Diurnal Variation of Potential Gradient for Same Time of Year in Different Oceans and in Different Latitudes.

Motivation for Cruise 7

Further frequent and widely distributed varying atmospheric electricity measurements were still sought

"…to settle the question whether such variations progress on the basis of universal time" (Ault, 1927).

A key improvement on the earlier cruises proposed was to employ continuous recording techniques, using a projection electrometer with photographic chart recording.

Cruise 7: oceanography and meteorology

Ault taking off "Nansen bottle", used to sample deep-sea water, 1928.

Pilot balloon weighing, prior to ascent, 1928

Ault releasing pilot balloon, to measure upper air currents, 1928.

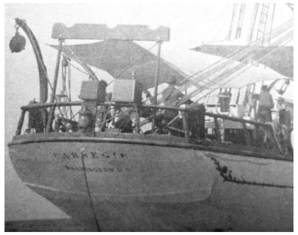
Sighting on pilot balloon with sextant and theodolite, 1929

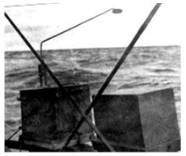
Ault in diving helmet, going down to disentangle bottom sample wire from hull, 1929

Carnegie Institution of Washington

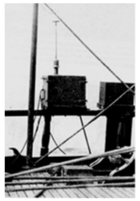
Continuous PG recording on Cruise 7

- Initially a sensor with continuous recorder was planned for the masthead, but became impractical from flexing of the hemp rigging.
- Site adjacent to the parasol collector on the stern rail used instead.

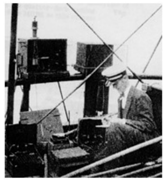




Bent collector rod used initially, projecting out over the water astern. (7th July 1928 to Nov 5th 1929)

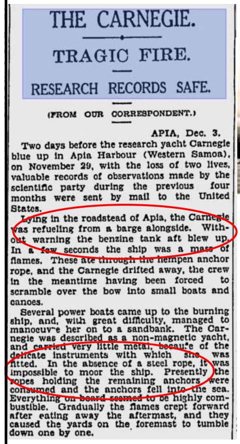


Vertical collector installed Nov 5th 1929.



Collectors in amber, 75cm above weatherproof wooden box housing fibre electrometer, microscope, light source, and motorised photographic recorder

Cruise 7 - tragedy



THE CARNEGIE.

TRAGIC FIRE.

RESEARCH RECORDS SAFE.

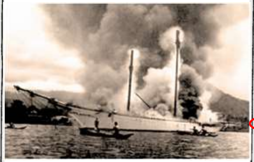
(FROM OUR CORRESPONDENT.)

APIA, Dec. 3.

Two days before the research yacht Carnegie blue up in Apia Harbour (Western Samoa), on November 29, with the loss of two lives, valuable records of observations made by the scientific party during the previous four months were sent by mail to the United States.

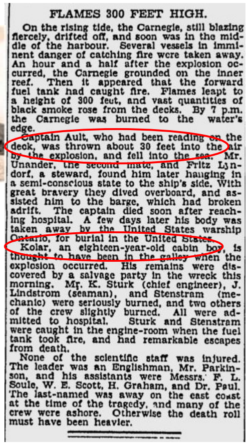
Lying in the roadstead of Apia, the Carnegie was refueling from a barge alongside. Without warning the benzine tank aft blew up. In a few seconds the ship was a mass of flames. These ate through the hempen anchor rope, and the Carnegie drifted away, the crew in the meantime having been forced to scramble over the bow into small boats and canoes.

Several power boats came up to the burning ship, and, with great difficulty, managed to manoeuvre her on to a sandbank. The Carnegie was described as a non-magnetic yacht, and carried very little metal, because of the delicate instruments with which she was fitted. In the absence of a steel rope, it was impossible to moor the ship. Presently the ropes holding the remaining anchors were consumed and the anchors fell into the sea. Everything on board seemed to be highly combustible. Gradually the flames crept forward after eating away the aftermast, and they caused the yards on the foremast to tumble down one by one.



November 29th, 1929, Apia Harbour (*Carnegie Institution*)

"The story of individual endeavour and enterprise, of invention and accomplishment, cannot be told." Captain J.P. Ault (August 26th, 1929) *Carnegie Institution of Washington Publication* 568, page iii



FLAMES 300 FEET HIGH.

On the rising tide, the Carnegie, still blazing fiercely, drifted off, and soon was in the middle of the harbour. Several vessels in imminent danger of catching fire were taken away. An hour and a half after the explosion occurred, the Carnegie grounded on the inner reef. Then it appeared that the forward fuel tank had caught fire. Flames leapt to a height of 300 feet, and vast quantities of black smoke rose from the decks. By 7 p.m. the Carnegie was burned to the water's edge.

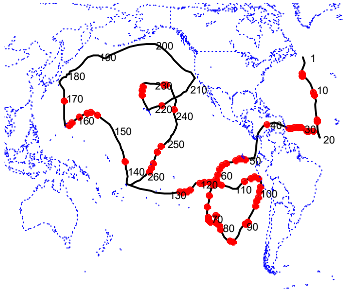
Captain Ault, who had been reading on the deck, was thrown about 30 feet into the air by the explosion, and fell into the sea. Mr. Unander, the second mate, and Fritz Lyndorf, a steward, found him later hanging in a semi-conscious state to the ship's side. With great bravery they dived overboard, and assisted him to the barge, which had broken adrift. The captain died soon after reaching hospital. A few days later his body was taken away by the United States warship Ontario, for burial in the United States.

Kolar, an eighteen-year-old cabin boy, is thought to have been in the galley when the explosion occurred. His remains were discovered by a salvage party in the wreck this morning. Mr. K. Sturk (chief engineer), J. Lindstrom (seaman), and Stenstram (mechanic) were seriously burned, and two others of the crew slightly burned. All were admitted to hospital. Sturk and Stenstram were caught in the engine-room when the fuel tank took fire, and had remarkable escapes from death.

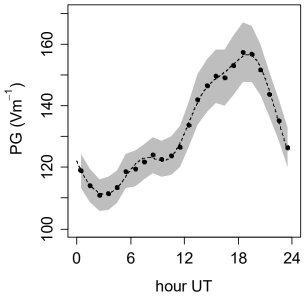
None of the scientific staff was injured. The leader was an Englishman, Mr. Parkinson, and his assistants were Messrs. F. L. Soule, W. E. Scott, H. Graham, and Dr. Paul. The last-named was away on the east coast at the time of the tragedy, and many of the crew were ashore. Otherwise the death roll must have been heavier.

The Sydney Morning Herald - Dec 13th, 1929

Cruise 7 observations

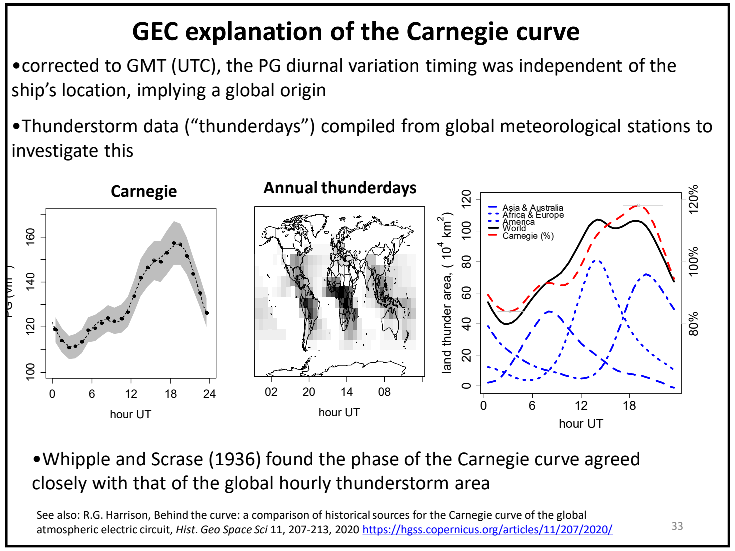


Number of days from outset marked: red points are those days which were subsequently identified as electrically undisturbed



- •From Aug 7th 1928 to Nov 18th 1929 the Carnegie was on open sea for 317 days, yielding 181 days of continuous PG data
- •5 reduction factor experiments (Kitts Point, (Maryland), Engey Island, (Reykavik), Bridgetown, (Barbados) Easter Island and Apia, Samoa)

R.G. Harrison, The Carnegie Curve *Surv Geophys* **34**, 2, 209-232, DOI: 10.1007/s10712-012-9210-2 (2013)



GEC explanation of the Carnegie curve

- corrected to GMT (UTC), the PG diurnal variation timing was independent of the ship's location, implying a global origin
- Thunderstorm data ("thunderdays") compiled from global meteorological stations to investigate this

- Whipple and Scrase (1936) found the phase of the Carnegie curve agreed closely with that of the global hourly thunderstorm area

See also: R.G. Harrison, Behind the curve: a comparison of historical sources for the Carnegie curve of the global atmospheric electric circuit, *Hist. Geo Space Sci* 11, 207-213, 2020 https://hgss.copernicus.org/articles/11/207/2020/

33

Radiowave confirmation of conducting layers

- If upper and lower spherical layers exist, they would provide a resonant cavity for electromagnetic waves, such as those excited by lightning discharges
- Schumann (1952) predicted that, for two concentric conducting spheres, the **Schumann resonance** frequency would be

$$f_n = \frac{c}{2\pi R_E}\sqrt{n(n+1)}$$

where *c* is the speed of light, R_E the radius of the earth and *n* the mode number

f_1 is predicted to be in the ELF at about 8Hz – this was found by Balser and Wagner (1962) at 7.8Hz

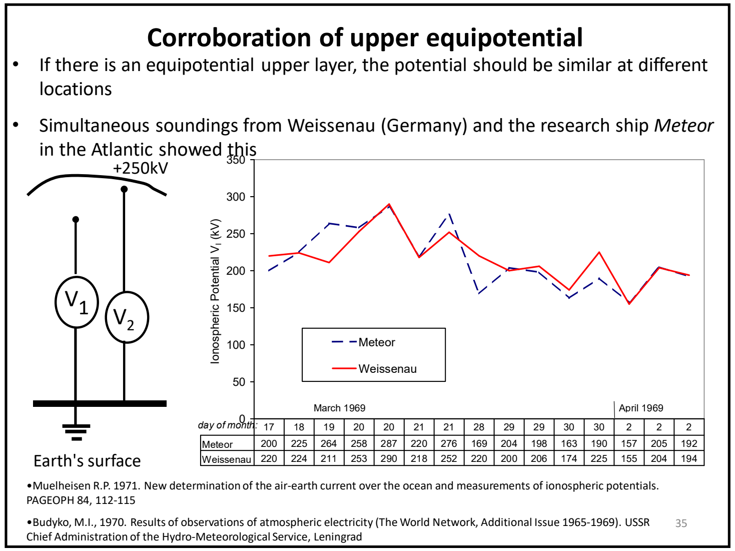
Small signal:

E ~300µV m^{-1}

B ~pT

34

34



Corroboration of upper equipotential

- If there is an equipotential upper layer, the potential should be similar at different locations
- Simultaneous soundings from Weissenau (Germany) and the research ship *Meteor* in the Atlantic showed this

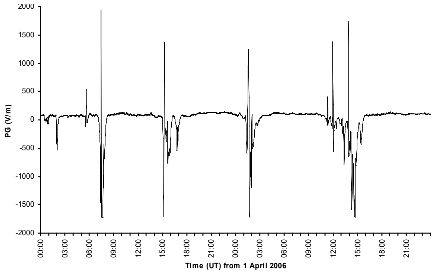
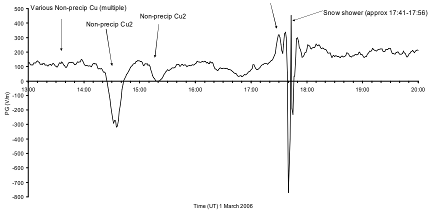
1. Potential Gradient (field mill, long wire antenna)
2. Air-earth current (Wilson apparatus, Lerwick plate, and GDACCS)
3. Air conductivity
4. Fair weather classification

PG - a very variable quantity

- With **thunderclouds** present, the PG obviously becomes highly variable.
- **But convective showers** and rainfall also lead to considerable variability
- And…even with low level layer cloud - no ice and minimal convection - the PG can be quite variable – is it due to space weather, or earth weather? --> reliable series of measurements are needed.





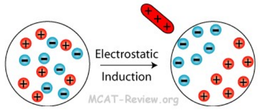
The field mill

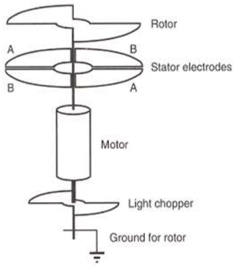
•Robust and durable instrument for measuring atmospheric **electric field**

•Horizontal plate electrode in which a charge is induced by the atmospheric electric field

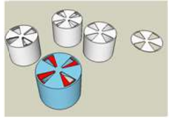
•This is compared with the charge induced under zero electric field conditions (when electrode covered).

=> Electrode is alternately covered and exposed by a mechanical shutter, which is driven by a motor – **synchronous detection** used to detect changes.





Operates continuously at the Observatory – see the real time graphs



Commercial field mills

- Electric field mills now widely commercially available
- Not so for other atmospheric electricity instruments

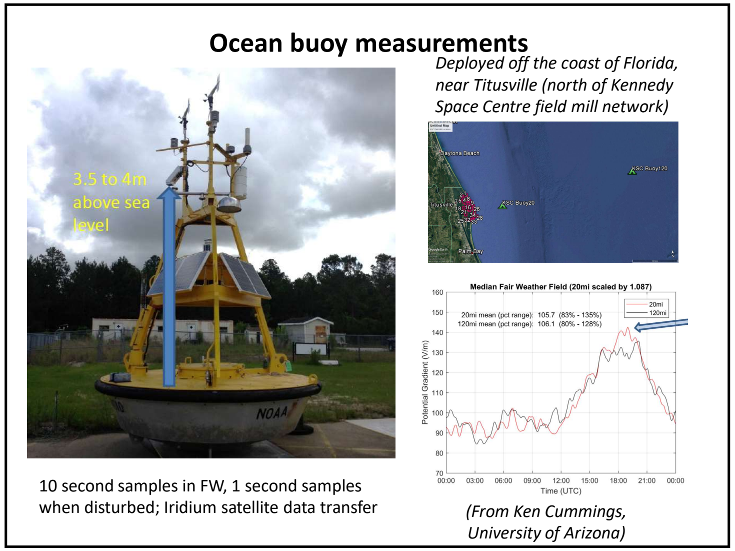
Instrument limitations - Antarctica

- Formation of fog (and sub zero temperatures) led to frost build up (riming) on British Antarctic Survey's own design of field meter



Ocean buoy measurements

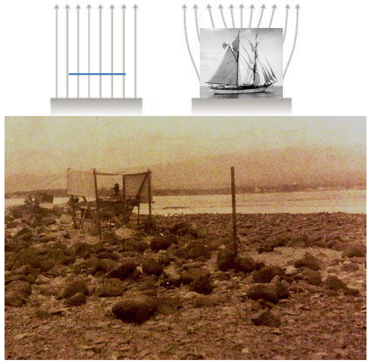
Deployed off the coast of Florida, near Titusville (north of Kennedy Space Centre field mill network)

10 second samples in FW, 1 second samples when disturbed; Iridium satellite data transfer

(From Ken Cummings, University of Arizona)

Standardisation – e.g. corrections for ship distortion

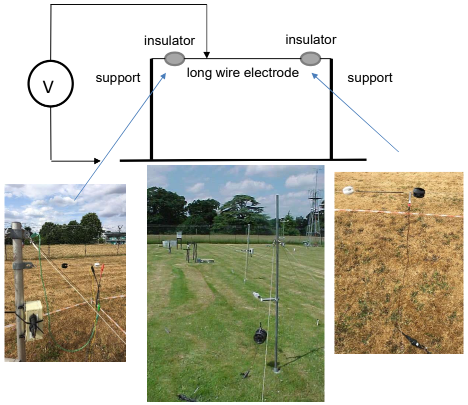
- On the **Carnegie voyages**, a “reduction factor” was needed to correct for the distortion of the ship and its rigging
- comparison made with flat shore sites close to level with the sea, free from trees, using a 15 to 20m long horizontal “passive wire” antenna
- Difficulty was in getting ship within half-mile…so reduction factor was measured often and averaged
- Reduction factor practically constant for PG 120 to 480V m^{-1}, 2.85 for mainsail up and boom to port or starboard, and 3.77 for mainsail down, with boom over port crutch



Potential Gradient “reduction-factor station”, Watson’s Island, Apia, Samoa (April 1929). Spiders caused frequent trouble by spinning webs in the cap of the shore electrometer and in the caps of the supporting insulators of the stretched wire system. “The spiders were numerous. Several hours of record were affected by the presence of spider webs.”

Passive wire antenna

- Ultra well-insulated horizontal wire positioned at known height naturally acquires the potential of the atmosphere

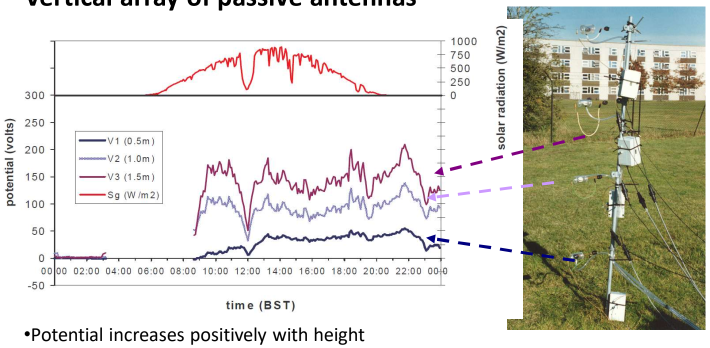


- Rate of acquisition of potential on the wire is not artificially accelerated by an equaliser
=> instrument is called the **passive wire**

- Wire potential measured using a high impedance voltmeter

- No calibration or geometrical corrections required as long as there are no distorting objects nearby =>value of PG at 1m measured using passive wire is considered absolute

Vertical array of passive antennas



- Potential increases positively with height
- Continuous turbulent mixing of ions is required for effective operation
- Note the effect of a cloud passing around noon BST

4. Variability in the global circuit

The global circuit is a planetary framework of electrical connectivity – it will also reflect variability of different kinds occurring in the atmospheric system, e.g.

- **Internal variability**. Changes in the thunderstorm and shower clouds which drive it, in terms of their positions and contributions. ENSO may influence these
- **External variability**. Cosmic rays provide much of the conductivity of air away from the surface. Factors which modulate cosmic rays – primarily solar changes – will lead to changes in the current flow.

This will **couple through into atmospheric processes** which use the global circuit in some way.

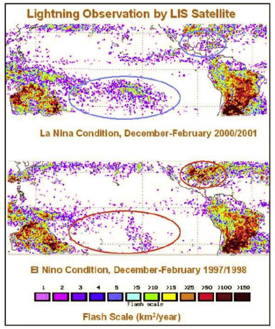
ENSO effects on lightning

- •Intensity, flash rate and location of lightning varies with ENSO timescale
- •10% change in global lightning flash rate from La Niña to El Niño



Lightning Observation by LIS Satellite
La Nina Condition, December-February 2000/2001
El Nino Condition, December-February 1997/1998
Flash Scale (km²/year)

More lightning in Pacific during(cool) La Niña phase than (warm) El Niño

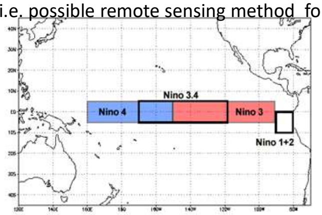
Complex relationship between regional variations in lightning and El Niño, La Niña . i.e. very location dependent

Satori G., et al, Variability of global lightning activity on the ENSO time scale, Atmospheric Research, 91, 500-507, 2009

ENSO effects on surface PG

GEC integrates effects of all thunderstorms active around globe

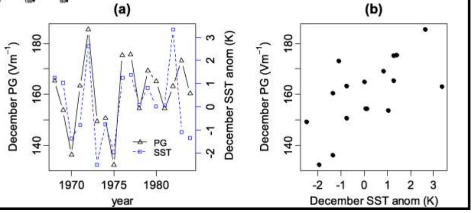
Signals from large scale variations may be seen in distant PG measurements i.e. possible remote sensing method for electrically active storms



Nino 4
Nino 3.4
Nino 3
Nino 1+2

Lerwick PG measurements compared to Niño 3.4 index (SSTs from area in Pacific ocean, bounded by 5°N-5°S and 120°-170°W)

Image from www.ncdc.noaa.gov

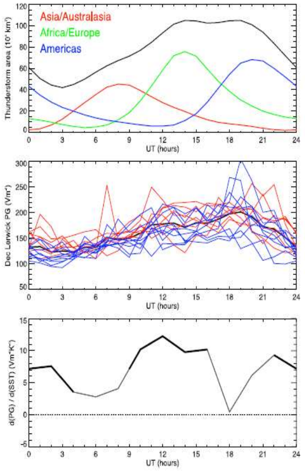


Remarkably strong correlation – PG large during El Niño and small during La Niña

Increase in GEC of 3.5% for 1K of SST anomaly

ENSO: Internal variability and Carnegie curve

El Niño Southern Oscillation shows a relationship with the Carnegie curve of the global circuit in atmospheric electricity – mean values increase with Pacific sea surface temperature

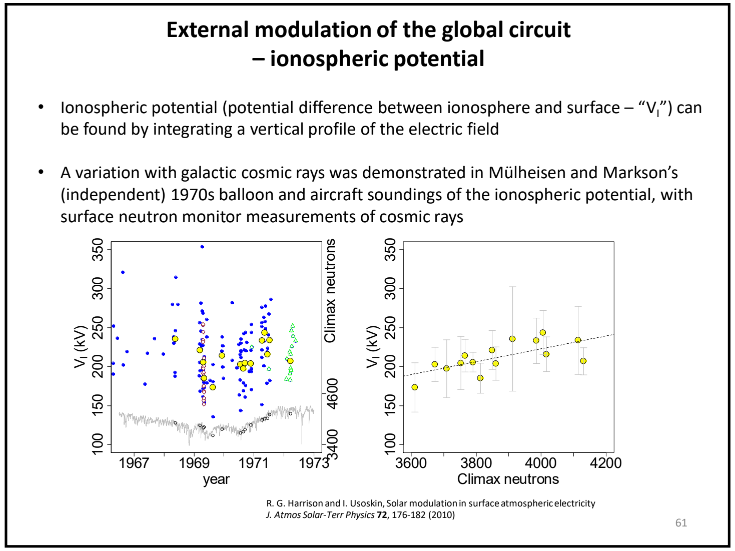


Red lines show Carnegie curve in atmospheric electricity at Lerwick (for December) during **El Niño** conditions, and *blue lines* during *La Niña*

→ sensitivity of ~ 5 Vm^{-1} K^{-1}

Greatest PG sensitivity to SST change is between 10-16UT => African lightning

R.G. Harrison, M. Joshi, K. Pascoe, Inferring convective responses to El Niño with atmospheric electricity measurements at Shetland *Environ Res Lett* 6 (2011) 044028



External modulation of the global circuit – ionospheric potential

- Ionospheric potential (potential difference between ionosphere and surface – "V_I") can be found by integrating a vertical profile of the electric field
- A variation with galactic cosmic rays was demonstrated in Mülheisen and Markson's (independent) 1970s balloon and aircraft soundings of the ionospheric potential, with surface neutron monitor measurements of cosmic rays

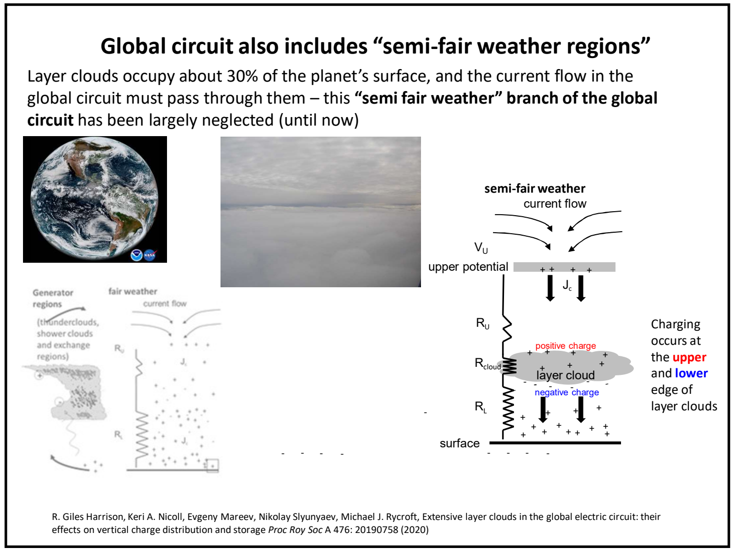
5. Applications and planetary global circuits



Global circuit also includes "semi-fair weather regions"

Layer clouds occupy about 30% of the planet's surface, and the current flow in the global circuit must pass through them – this **"semi fair weather" branch of the global circuit** has been largely neglected (until now)

Characteristics of the Martian global circuit

- Driven by discharges in dust storms
  - Two types of discharge predicted: “volcanic lightning” and also a weaker glow discharge
  - Strong seasonality (Farrell and Desch, *JGR*, 2001)
    - **In storm season, surface *E* = 475 Vm^{-1} and J_c = 1.3 nAm^{-2}**
    - **Outside storm season, surface E = 0.14 Vm^{-1} and J_c = 0.4 pAm^{-2}**
- **Current flow is in the opposite direction to Earth**
  - Atmospheric composition favours formation of CO_2^- ions and is tenuous enough for free electrons to exist
  - Interesting consequences of variable magnetic field
  - Surface conductivity is the major uncertainty for existence of global circuit
- No measurements yet
  - ExoMars “Franklyn” rover has radio sensors for lightning on Mars

CONFIRMING IDEAS

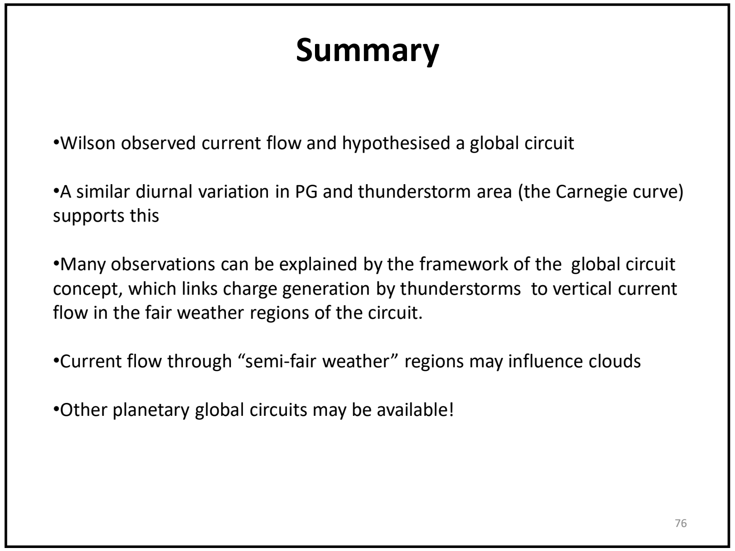
PG daily variations in Universal Time are consistent at many locations (*Carnegie* curve) and **follow global thunderstorm distribution** (Whipple 1929, Whipple and Scrase 1936)

Surface and ionosphere and act as a **resonant cavity** that is **excited by em waves from lightning** (Schumann 1952, Schumann and König, 1954)

Ionospheric potential measured at different locations vary together *i.e.* **ionosphere equipotential** (Mülheisen 1971)

Ionospheric potential shows Carnegie curve (Mülheisen 1971)

75



Summary

•Wilson observed current flow and hypothesised a global circuit

•A similar diurnal variation in PG and thunderstorm area (the Carnegie curve) supports this

•Many observations can be explained by the framework of the global circuit concept, which links charge generation by thunderstorms to vertical current flow in the fair weather regions of the circuit.

•Current flow through “semi-fair weather” regions may influence clouds

•Other planetary global circuits may be available!

Abstract

The study of the global atmospheric electric circuit has advanced dramatically in the past 50 years. Large advances have been made in the areas of lightning and thunderstorm research, as related to the global circuit. We now have satellites looking down on the Earth continuously, supplying information on the temporal and spatial variability of lightning and thunderstorms. Thunderstorms are electric current generators, which drive electric currents up through the conducting atmosphere. They maintain the ionosphere at a potential of $\sim+250$ kV with respect to the Earth's surface. The global electric circuit is completed by currents $\sim$2 pA/m^2 flowing through the fair weather atmosphere, remote from thunderstorms, and by transient currents due to negative cloud-to-ground lightning discharges. The time constant of the circuit, $\sim > 2$ min, demonstrates that thunderstorms must occur continually to maintain the fair weather electric field. New discoveries have been made in the field of sprites, elves and blue jets, which may have a direct impact on the global circuit. Our knowledge of the global electric circuit modulated by solar effects has improved. Changes to the global circuit are associated with changes of conductivity linked with the time-varying presence of energetic charged particles, and the solar wind may influence the global electric circuit by inferred effects on cloud microphysics, temperature, and dynamics in the troposphere. We now have a better understanding of how the conductivity of the atmosphere is influenced by aerosols, and how this impacts our measurements of the fair-weather global circuit. The global atmospheric electric circuit is also beginning to be recognised by some climate researchers as a useful tool with which to study and monitor the Earth's changing climate. © 2000 Elsevier Science Ltd. 1. Introduction to the global atmospheric electric circuit

One of the first, and certainly the most famous, demonstrations of a reproducible variation with Universal Time is the hourly average curve of electric potential gradient in the lowest atmosphere obtained over the world's oceans on the Carnegie cruises. These curves have long served as de facto standards (see Bering et al., 1998) with which to evaluate the viability of attempts to measure worldwide variations of electrical properties of the atmosphere near the Earth's surface.

The thunderstorm generator hypothesis proposed by Wilson (1920) was based on his observations that, beneath the thundercloud, negative charge is transferred to the Earth and above the thundercloud positive charge is transferred to the conducting upper atmosphere. A subsequent discovery was the close correlation between the diurnal (Universal Time) variation of the thunderstorm generator current (represented by the frequency of thunderstorm occurrence) and the load current (represented by the fair-weather ground electric field, or air-Earth current density), integrated over the surface of the Earth.

By making measurements in regions where local diurnal variations of atmospheric conductivity are minor, by excluding data collected during periods of local meteorological influence, and by averaging to remove the day-to-day variability of global thunderstorm activity, a diurnal curve with a peak near 18 UT, a minimum near 03 UT and a range of some 30% of the mean was obtained. This is known as the global, 'fair-weather', diurnal variation, or the 'Carnegie curve'. Bering (1995) gives a comprehensive interpretation of recent advances in this area.

Humans are becoming increasingly concerned about changes — both natural and anthropogenic — in the Earth's environment. Particular attention is being paid to the atmosphere, not only the troposphere, the region of the Earth's weather and climate, but also the stratosphere — above it, which is where the ozone layer is. The springtime Antarctic ozone depletion, the so-called ozone hole, is the most popular example (see Farman et al., 1985; Rycroft, 1990; Solomon, 1999). Changes higher up, in the mesosphere, thermosphere and ionosphere may also be important.

How does atmospheric electricity affect man and his technological systems? Is our electrical environment changing significantly as a result of air pollution, the release of radioactive materials, the construction of high-voltage power lines, and other activities, or by energetic charged particle effects in the atmosphere? It is clear that modern technological advances may be seriously affected by various electrical processes in the atmosphere or in space, and also that man is beginning to affect the electrical environment in which he resides.

2. Physics of the global atmospheric circuit

Atmospheric electricity plays various roles in the highly coupled system representing the Earth's atmosphere and the near-Earth space environment. For further background information, see Herman and Goldberg (1978).

The conductivity of the fair-weather atmosphere near the surface is on the order of 10^{-14} mho/m, and it increases nearly exponentially with altitude up to 60 km, with a scale height of about 7 km. The main charge carriers below about 60 km are small positive and negative ions that are produced primarily by galactic cosmic rays. Above 60 km, free electrons become more important as charge carriers and their high mobility abruptly increases the conductivity throughout the mesosphere. Above 80 km, the conductivity becomes anisotropic because of the influence of the geomagnetic field, and there are diurnal variations due to solar photoionization processes. The arena for the subject is included in the system shown in Fig. 1, which shows the Earth at the centre, surrounded by the atmosphere, ionosphere, the van Allen belts and magnetosphere deformed by the flowing solar wind.

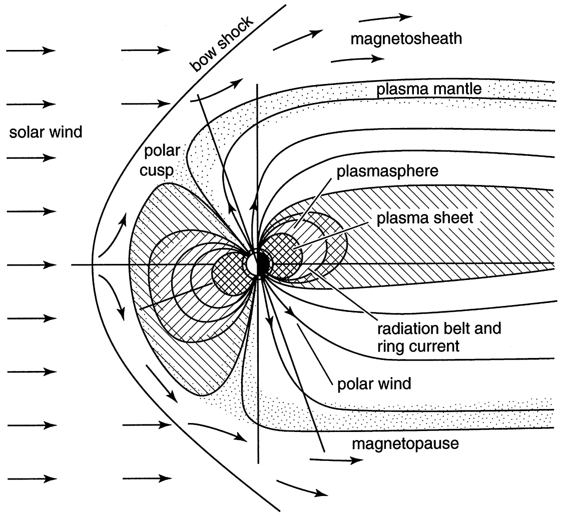

Fig. 1. Diagram showing the Earth at the centre, surrounded by the atmosphere, ionosphere, the van Allen radiation belts and magnetosphere deformed by the flowing solar wind (from Davies, 1990).

The area for the subject of atmospheric electricity is the electrically insulating concentric shell between the highly conducting Earth and the highly conducting ionosphere (see Fig. 2); this is surrounded by "magnetospheric action". Fig. 3, from Markson (1978), shows that the global electric circuit is believed to be driven by the upward current from thunderstorms, 1000 of them occurring around the globe at any one time. They occur mostly at low latitudes, over tropical land masses, in the local afternoon and evening. The more energetic thunderstorms reach higher into the atmosphere.

It has been known for over two centuries that the solid and liquid Earth and its atmosphere are almost permanently electrified. The surface has a net negative charge, and there is an equal and opposite positive charge distributed throughout the atmosphere above the surface. The fair-weather electric field is typically from 100 to 300 V/m at the surface; there are diurnal, seasonal, and other time variations in this field that are caused by many factors. The atmosphere has a finite conductivity that increases with altitude; this conductivity is maintained primarily by galactic cosmic ray ionization. Near the Earth's surface, the conductivity is large enough to dissipate any field in just 5–40 min (depending on the amount of pollution); therefore, the local electric field must be maintained by some almost continuous current source.

According to the classical picture of atmospheric electricity, the totality of thunderstorms acting together at any time charges the ionosphere to a potential of several hundred thousand Volts with respect to the Earth's surface. This potential difference drives a vertical electric conduction current downward from the ionosphere to the ground in all fair-weather regions of the globe. The fair weather electric conduction current varies according to the ionospheric potential difference and the columnar resitance between the ionosphere and the ground. Horizontal currents flow freely along the highly conducting Earth's surface and in the

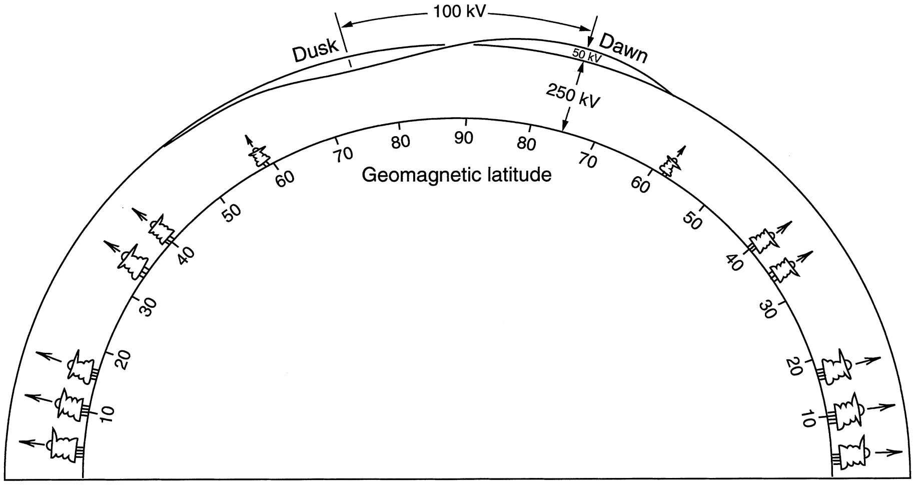

Fig. 2. Diagram showing the upward current to the ionosphere generated by thunderstorms; the ionosphere is approximately an equipotential surface, at +250 kV with respect to the Earth's surface (from Markson, 1983).

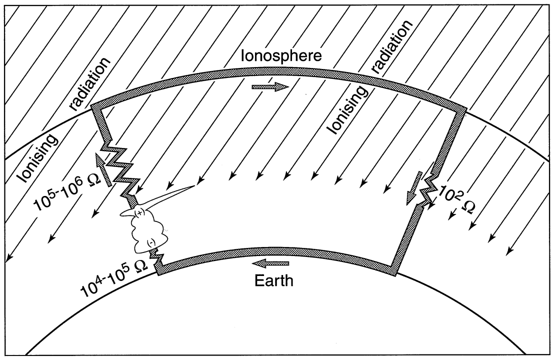

Fig. 3. Diagram of the global electric circuit (bold); the current flowing in the circuit is determined mainly by the current in the generator representing the sum of thunderstorms around the world, in the charging resistor above, and in the resistor representing more than the boundary layer below. Also important are increases in the ionising radiation which, from time to time, reduce the conductivity of the middle atmosphere (from Markson, 1978).

ionosphere. A current flows upward from a thunderstorm cloud top toward the ionosphere and also from the ground into the thunderstorm generator, closing the circuit. The global fair-weather load resistance is of the order of 100 Ω, as indicated in Fig. 3.

A few measurements have been made that give the magnitude of the current flowing upward over the whole area of a thundercloud (Kasemir, 1979). The currents range from 0.1 up to 6 A, with an average between about 0.5 and 1 A per thunderstorm cell (Blakeslee et al., 1989).

The topic is not as simple as it seems initially — there are many variations. It is a problem of global scale, but with spatial variations of important parameters, on the regional scale (e.g. in the geomagnetic latitude, or geographic longitude), on the local scale, and also with altitude. At higher geomagnetic latitudes, the conductivity of the air, σ, is larger due to the larger flux of ionising radiation there due to cosmic rays ($\sim > 1$ GeV ions) or to relativistic charged particle precipitation from the magnetosphere (> 1 GeV ions or > 1 MeV electrons). The cosmic ray fluxes are somewhat reduced at the time of a Forbush decrease and, for certain geomagnetic storms, the fluxes of magnetospheric origin are enhanced.

Fig. 3 illustrates one thunderstorm representing all 10^3 active thunderstorms occurring over less than 1% of the Earth's surface, and each generating $\sim$1 A. Thus, an upward current of $\sim$1 kA is driven through the "charging resistor", of 10^5–10^6 Ω. This current flows through the almost perfectly conducting ionosphere. The return current of 1 kA flows through the fair weather atmosphere, over 99% of Earth's surface remote from thunderstorms; the "discharging resistor", or load resistor, has the value $\sim 2 \times 10^2$ Ω globally.

It is generally convenient to regard the highly (but not perfectly) conducting ionosphere as an equipotential surface locally, at a potential of about +250 kV with respect to the Earth. However, the ionosphere is not an equipotential surface globally, because of

- the dawn-to-dusk potential difference (up to $\sim$100 kV) across the polar cap arising from the interaction of the solar wind with the magnetosphere (see Fig. 2), which causes the two-cell convection pattern of the polar F-region,
- potential differences (up to $\sim$100 kV) associated with auroral/magnetospheric processes,
- unipolar induction, due to the rotation of the Earth's magnetic field, so that the equator is at a potential of −91 kV with respect to the pole, in the centred dipole approximation, in an inertial frame of reference, and

- dynamo action in the ionosphere, such as the Sq process (up to ∼20 kV).

The theoretical foundations of the subject of atmospheric electricity are firm, being based on the laws of physics — the Navier–Stokes and continuity equations, and the laws of thermodynamics — which are required to understand and predict atmospheric motions. The atmospheric density decreases exponentially with increasing height, with a scale height, $H \sim 7$ km. The atmospheric conductivity σ increases with height due to the energy spectrum of the cosmic rays and the charged particles precipitating from the magnetosphere. By Ohm's law, which is valid for linear processes only,

$$J = \sigma E, \tag{1}$$

where J is the vertical electric current density and E is the vertical electric field. This leads us to expect that, in order to maintain current continuity, E is largest near the Earth's surface, where its value is, from observations, ∼130 V/m. It decreases upwards, exponentially. By Gauss' law, there is a space charge profile associated with this electric field.

Cho and Rycroft (1998) have presented a simple model profile for the atmospheric conductivity, ranging from near 10^{-13} mho/m near the surface to 10^{-7} mho/m at 80 km altitude in the lower ionosphere. Hale (1994) has presented more complex profiles, which show variations in both space and time.

Only a few mathematical models of global atmospheric electricity have appeared over the years (Kasemir, 1963, 1977; Hill, 1971; Hays and Roble, 1979; Volland, 1982; Ogawa, 1985). Since it is difficult to obtain global measurements to deduce the instantaneous properties of the global circuit, these models provide a convenient means of examining, through numerical experiments, the various interacting processes operating in the global circuit. The overall success of the models may be judged by how well they represent the observed atmospheric electrical properties at any place and time within the circuit.

Thunderstorms are extremely complex, and some simplifying assumptions must be made to represent their properties in a global model. The usual assumption is to consider thunderstorms as dipolar current sources, with a positive source in the could top and a negative source in the cloud bottom.

Ogawa (1985) has considered the simple equivalent circuit for the atmosphere shown in Fig. 4. With R_1 being the charging resistor mentioned earlier, R_2 the resistance of the thunderstorm generator where there exist potential differences ∼100 MV between the positively charged top of the thundercloud and the negatively charged bottom, and R_3 the resistance of the boundary layer (first few km) of the atmosphere, all of which are much greater than r, the resistance of the fair-weather atmosphere, it follows that

$$I = R_2 I_0/(R_1 + R_2 + R_3). \tag{2}$$

Eq. (2) relates the current through the fair-weather atmosphere, I, to the current in the thunderstorm generator, I_0.

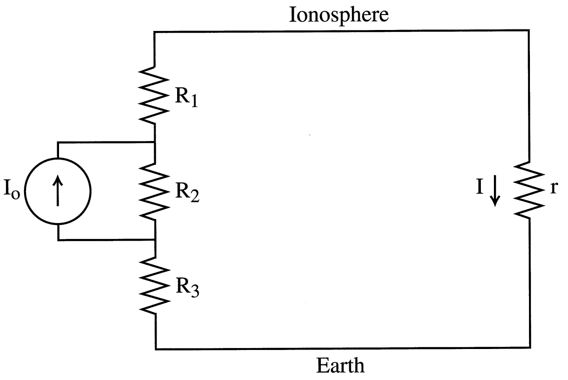

Fig. 4. A simplified equivalent circuit of the global electric circuit, showing the net thunderstorm generator current, I_0, and the fair weather current I (from Ogawa, 1985).

It is clear that R_1 and R_3 are particularly important in this relation; R_3 can be significantly reduced by

- point discharge currents due to the very large electric field below the thundercloud, in the region of updraughts, and
- increasing the height of the ground surface above mean sea level.

In this regard, measurements of I at a high-altitude (mountain) observatory remote from active thunderstorms can give some information on I_0 if R_1 and R_2 can be considered to be constant. Both may, however, be reduced at times of enhanced fluxes of energetic charged particles associated with enhanced geomagnetic activity. And the contribution to R_1 above an active, sprite-producing thundercloud may be greatly reduced due to the ionisation (see Cho and Rycroft, 1998) produced in the rarefied mesosphere by the large transient electric fields due to large, positive cloud-to-ground lightning discharges.

Fig. 5 is a new diagram, the upper part of which attempts to illustrate the electric currents flowing through different parts of the atmosphere, and including the magnetosphere above. The lower part of the diagram shows the equivalent circuit, with three different fair weather regions. One of these is for a high altitude part of the Earth where the profiles of J and E through the fair weather atmosphere will differ from those elsewhere.

From standard electrostatic theory, the capacitance C of the concentric shell of atmosphere between the Earth and the ionosphere, over one scale height of atmosphere rather than over the full height of the ionosphere, is given by

$$C = 4\pi\varepsilon_0 R_{\mathrm{E}}^2/H \sim 0.7 \text{ F}, \tag{3}$$

where R_{E} is the radius of the Earth and ε_0 is the permittivity of free space.

Hence the time constant for the atmospheric global electric circuit, t, is given by

$$\tau = Cr \sim 2 \text{ min}. \tag{4}$$

Fig. 5. (a) Top. Diagram, approximately to scale, showing electric currents (bold arrows) flowing up from the net thunderstorm generator over $\sim<1\%$ of the Earth's surface, through the ionosphere, the fair-weather atmosphere and the Earth, and closing as point discharge currents below the thundercloud. In the centre, the distribution of positive space charge is shown. (b) Bottom. The equivalent circuit for (a), showing components of the fair-weather resistor over different height ranges for 2–3 km above the surface; the boundary layer resistor is "missing" above a mountain or over Antarctica. Typical numerical values are also shown.

With a charge of 200 C associated with each thunderstorm, the total Q on the plates of the spherical condenser is 2×10^5 C. Thus, the energy associated with the global electric circuit is enormous; it is

$$W = CV^2/2 \sim 2\times10^{10}\ \mathrm{J}, \tag{5}$$

inserting $V = 250$ kV.

The electric current density through the fair-weather atmosphere, J, has the value $\sim 2\times10^{-12}$ A/m^2. Taking the conductivity of air at ground level, produced by extremely energetic cosmic rays and by radon from the ground, and due to aerosols, to be $\sim 2\times10^{-14}$ mho/m, the fair weather electric field at ground level is $\sim 10^2$ V/m, close to the near observed value of 130 V/m. At 20 km altitude, the fair-weather vertical electric field is ~ 1 V/m, and can be well measured from balloons. At 50 km altitude, it is only $\sim 10^{-2}$ V/m.

Following a Forbush decrease, the atmospheric conductivity everywhere could be reduced by $\sim 10\%$. If J is unchanged, the ionospheric potential, and hence also the fair weather electric field, may be increased by $\sim 10\%$. There is some observational evidence to support this concept (see Ogawa, 1985).

After a sprite above one of the thousand active thunderstorms, the ionospheric potential would reduce to 99.9% of its initial value for a millisecond or so. Thus, it is evident that sprites are unlikely to cause an observable effect on the fair-weather electric field.

To consider electrodynamic or electromagnetic effects rather than electrostatic phenomena, Maxwell's equations are involved. They relate electromagnetic fields to charge and current densities in a time-varying situation. Electromagnetic waves of appropriate frequencies can be generated, and these propagate away. The medium through which the energy propagates has a certain refractive index, which is equal to the square root of the relative electric permittivity.

The medium is treated as a conductor at frequencies (ω) such that $\omega \ll \sigma/\varepsilon_0$. Alternatively, the medium behaves as a leaky dielectric when $\omega \gg \sigma/\varepsilon_0$; that is the situation in the ionosphere for VLF waves and for higher frequency waves. However, for waves at Schumann resonance frequencies the lower ionosphere behaves like a conductor. Radiation produced by the current pulse due to a cloud-to-ground lightning discharge (i.e. due to the rapid destruction of the dipole moment formed by the negative charge in the bottom of a thundercloud and its positively charged image in the Earth) ranges from Schumann resonance frequencies up to ~100 MHz.

However, if there are no radiation effects to be considered, the current flowing is the sum of the conduction current and the displacement current. This is termed the Maxwell current. In the atmosphere, there can be other significant contributions to the current density, due to convection, turbulence, precipitation (or settling) or point discharges. Mentioned earlier, and sometimes called St. Elmo's fire, this last contributor to the current through the global atmospheric circuit may actually carry half the current (see Bering et al., 1998). By its very nature, it is variable, and not a great deal is known about it. It is a topic for further research.

A fundamental property of the global atmospheric electrical circuit is the electrical relaxation time at various altitudes, which is defined as the time the electric current takes to adjust to $1/e$ of its final value after an electric field is suddenly applied, assuming that the conductivity remains constant. At high altitudes, near 70 km, the relaxation time is about 10^{-4} s, increasing with decreasing altitude to about 4 s near 18 km and to about 5–40 min near the Earth's surface. The electrical relaxation time of the land surface of the Earth is about 10^{-5} s. The maximum value of about 40 min in the atmosphere near the Earth's surface is the characteristic time that the global circuit would take to discharge if all thunderstorm activity suddenly ceased. Measurements have never shown a complete absence of a fair-weather electric field for any length of time, thereby suggesting a continuous operation of thunderstorms and other generators in maintaining the currents flowing in the global circuit. For time variations longer than about 40 min a quasi-static approximation can be applied when modelling the electrical properties of the global circuit.

3. Solar and cosmic influences on atmospheric electricity

3.1. Solar cycle effects

Variable plasma phenomena from the Sun, such as gigantic coronal mass ejections, can create geomagnetic storms, periods of enhanced geomagnetic activity. Such phenomena exert a profound — often disruptive, and occasionally devastating — influence on humankind's technological systems, such as satellites, telecommunications systems, power lines and pipelines; they may even affect human health.

It is well known that the Sun is not a constant star but one whose radiative output (especially in the ultraviolet and X-ray spectral regions) varies over a solar cycle, of ~11 years period. (Taking account of the Sun's magnetic polarity, it is actually a ~22 year cycle.) The temperature, and hence the density, of the upper atmosphere (thermosphere) vary markedly over a solar cycle. For example, at ~400 km altitude where the International Space Station will operate, the density — and hence the drag force — is almost a hundred times greater at solar maximum than at solar minimum.

The solar magnetic field and its extension through the interplanetary medium (carried by the plasma of the solar wind) to the Earth's orbit and beyond, into the heliosphere, is markedly more variable at solar maximum than at solar minimum. Thus, the flux of galactic cosmic rays (scattered by the irregularities of the interplanetary magnetic field) entering the top of the atmosphere is some tens of percent larger at solar minimum that at solar maximum, whereas the flux of energetic (>0.1 GeV) charged particles (protons) from the Sun at solar minimum is typically many times less that its value at solar maximum. Both types of energetic charged particles and also energetic charged particles precipitating from the inner and outer magnetospheric radiation belts (see Fig. 1, from Davies, 1990) during geomagnetically active periods interact with the Earth's middle and lower atmosphere by depositing their energy in the atmosphere, by creating ionisation directly or via bremmstrahlung radiation, by altering its chemistry (particularly ozone, nitric oxide and sulphate aerosols, see Jackman et al., 1995), or by affecting the nucleation of water droplets to form clouds (see Tinsley, 1996, 2000). There is some recent evidence that energetic solar protons appear to produce small holes in the Arctic ozone layer. They may trigger the formation of cirrus clouds which decrease the flux of solar radiation to the Earth's surface and hence affect the evolution of weather systems (see Pudovkin and Babushkina, 1992), and also affect the Earth's radiation budget by contributing to the greenhouse effect (also see Svensmark and Friis-Christensen, 1997),

Ground-based radars and other instruments in Scandinavia and around the world observe the effects of the ever changing, million Ampere current systems in the auroral ionosphere at heights near 110 km. These cause changing geomagnetic fields which induce large and varying currents to flow in long conductors, such as electrical power lines or oil pipe lines, sometimes with catastrophic effects. These include exploding transformers and power cuts (outages) of several hours duration, or corrosion.

Thus atmospheric electricity plays various roles in the highly coupled system representing the Earth's atmosphere and the near-Earth space environment. There are temporal variations, on time scales varying from microseconds (in lightning discharges), to milliseconds (e.g. sprites), minutes to an hour (e.g. thunderstorm regeneration), hours to a day (e.g. diurnal variations), months (solar rotation and seasonal effects), and to a decade (solar cycle effects), as well as spatial variations.

3.2. Latitudinal effects

Solar influences on the geoelectric field differ between mid-latitudes and the polar regions (Tinsley, 1996).

Increased solar activity reduces galactic cosmic ray fluxes in mid-latitudes, thus reducing the atmospheric conductivity in this region, while at the same time solar protons may be "funnelled" by the Earth's magnetic field to polar regions resulting in an increased atmospheric conductivity there. A dawn-to-dusk potential difference is also applied across the polar regions as a result of the interaction of the solar wind and the Earth's magnetic field (see, for example, Tinsley and Heelis, 1993). The cross-polar potential results from the same interactions that generate auroral activity and typical lies in the range 30–60 kV (Fig. 2). It may, at times of increased solar activity, exceed 100 kV. The cross-polar potential may not be the dominant solar influence on the global geoelectric circuit, but it is of significant magnitude in the polar regions. The diurnal pattern generated as a station rotates beneath the cross-polar cap potential difference also aids its detection.

The global electric circuit is closed by currents flowing in the ionosphere. At high latitudes, within the polar cap, these currents are strongly influenced by parameters of the solar wind, particularly the direction of the interplanetary magnetic field. In the auroral zone, the ionosphere is markedly disturbed when the magnetosphere is buffeted by a cloud of solar wind of enhanced density which is associated with a huge coronal mass ejection event from the Sun. As a result, the potential difference across the polar cap ionosphere can vary markedly.

The measurement techniques applied in magnetospheric and ionospheric research enable the detection of strong, intrinsic effects of the solar wind/ionosphere on the electrical potential distribution and conductivity of the atmosphere, as presented by Michnowski (1998). These manifestations of the solar wind interaction with the magnetosphere and ionosphere are especially evident at high latitudes.

4. Aerosols and the global circuit

4.1. Planetary boundary layer (PBL) aerosols

The planetary boundary layer (PBL) is the lowest few kilometers of the atmosphere, where interactions with the surface, man, and the biosphere are the most pronounced. Near land surfaces the ionization is, beside galactic cosmic rays, produced by the decay of natural and artificial radioactivity. Electrical processes in the PBL are complex, highly variable, and span a tremendous range of space and time scales. The electrical variables respond to many of the lower atmospheric processes but usually have little influence on the phenomena to which they respond. Within the PBL, local turbulent fluctuations of space-charge density impose a time-varying electric field that is comparable in magnitude with, or even greater than, the electric field maintained by global thunderstorm activity. Since the PBL is the region of the atmosphere with the greatest resistance, it is this layer (as well as the thunderstorm generators) that control the currents in the global circuit. Boundary layer processes can have a substantial impact on the fields and currents appearing throughout the entire atmospheric column from the Earth to the ionosphere. Modelling of the atmospheric electricity in the PBL is difficult due to the complicated conditions in the PBL (see Hoppel et al., 1986).

Aerosol particles can change the Earth's radiation budget both directly through scattering and through absorption and indirectly through modification of cloud microphysical properties. It is clear that there is a great uncertainty in assessing the direct and indirect effect of aerosols on climate change. We must understand and be able to quantify the most important sources and characteristics of aerosols in order to assess their effects on climate change. The relatively short residence time of aerosols in the troposphere, of order of a few days, results in significant spatial and temporal variations in aerosol particle concentration, size and composition. The high variability of the atmospheric aerosol leads to one of the largest uncertainties of anthropogenic climate forcing. This variability is compounded by a lack of much information on the properties of the atmospheric aerosols prior to the late 1970's when commercial aerosol instrumentation became more widely available. Thus, it is difficult to assess the influence of anthropogenic aerosols on radiative forcing up to that time. However, a number of researchers have shown that atmospheric electricity parameters can act as a good indicator or surrogate.

Many factors affect the electrical conditions in the PBL. An important area of research is the study of atmospheric ions. According to their physical nature, atmospheric ions with mobilities above 0.5 $\mathrm{cm}^2\ \mathrm{V}^{-1}\ \mathrm{s}^{-1}$ are charged molecular clusters or cluster ions. Tammet et al. (1992), Horrak et al. (1998) and others have shown the importance of these charged particles in atmospheric electricity, particularly in relation to atmospheric conductivity and to space charge formation. Retalis and Retalis (1998) treated the effects of air pollution on the large ion concentration, which indicated the importance of polluted areas (like cities, etc.) on the electrical environment. The impact of Chernobyl in April 1986 on all atmospheric electrical parameters in some parts of Sweden has been significant directly after the accident and several months later (Israelsson and Knudsen, 1986). Martell (1985) and Israelsson et al. (1987) have shown the importance of the ionisation from natural and artificial radioactivity in the charging mechanism of clouds.

Even natural processes over the sea are of importance. Blanchard (1963) indicated that currents as large as hundreds of Amperes flow from the ocean surface into the atmosphere as a result of electrified droplets that are ejected from the bursting of small bubbles.

Modelling of convection currents has shown that they only become important in unstable mixed layers, where the turbulent transport time across the entire PBL can be comparable with the electrical relaxation time. Willett (1978) showed that, on average, the convection currents act as a local generator capable of reducing the total downward current density by as much as 44%.

In order to study the horizontal structure of vertical current densities in the PBL, experiments to examine the covariation of atmospheric vertical electric currents at different stations using long-wire antennas are discussed by Israelsson et al. (1994).

4.2. Volcanoes and aerosols above the PBL

The main source of ionisation in the mid-troposphere and stratosphere (above the PBL) is cosmic radiation. The ionisation rate depends on magnetic latitude and on solar activity. The composition of the ions that establish the bulk electrical properties is relatively unknown. The ion concentration is also affected by aerosols whose distributions are quite variable in both space and time.

The global electric circuit varies over the solar cycle associated with cosmic ray flux changes. Whilst the contributions of thunderstorms may not only be to maintain an upward DC current, an improved understanding is required of the return current (~ 2 pA/m^2) flowing through the "fair-weather" atmosphere as part of the global electric circuit, particularly for geographically restricted variations of atmospheric conductivity. Another type of perturbation to the atmosphere results from volcanoes. Their sulphate aerosols and dust particles could nucleate high-altitude clouds, and the sulphates change the atmospheric conductivity and hence the properties of the global electrical circuit.

The character of upper tropospheric aerosols can be temporarily disturbed not only by volcanic eruptions but also by forest fires, biomass burning, and large dust storms. In addition annual variations of their concentrations have also been observed (Hofmann et al., 1975). Another important temporal variation of tropospheric aerosols is associated with the so-called Arctic haze events. New evidence suggests that these events are characterized by high particle loading throughout a large portion of the troposphere. The impact of this extensive aerosol loading on atmospheric electrical parameters is yet to be determined.

Hogan and Mohnen (1979) reported the results of a global survey of aerosols in the troposphere and lower stratosphere. They found that the concentrations were more or less symmetrically distributed about the Earth. More measurements of this type could provide the basis for extrapolating local or isolated observations to characteristic worldwide values. Man-made global ionisation effects reported by Boeck (1983), who studied the effect of krypton 85 released into the atmosphere on the global conductivity, have to be included in the global electric circuit.

The morphology of stratospheric aerosols is dominated by a persistent structure frequently referred to as the 20-km sulphate layer, or Junge layer. It is now known that the character of this layer is highly affected by large volcanic eruptions (Gringel et al., 1986). These volcanic eruptions can result in a rather dramatic increase of the aerosol content up to the stratosphere. The extent to which these aerosols directly affect the atmospheric conductivity, small-ion concentration, and mobility should be investigated to a greater extent. On the other hand, the sulphuric acid content of the lower atmosphere is also drastically enhanced following volcanic eruptions and might influence the ion composition considerably. Air-Earth current density measurements seem to be consistent with the classical picture of the global circuit, with some exceptions. The question of whether there are other global generators in the lower atmosphere, in addition to thunderstorms, could probably be unravelled by ground-based and balloon-borne current measurements at different locations.

5. Thunderstorms and the global circuit

5.1. Spatial and temporal distribution of thunderstorms

In recent decades we have greatly advanced our knowledge regarding the spatial and temporal distribution of thunderstorms and lightning. In the 1960s the first satellite observations of lightning were obtained (Vorpahl et al., 1970). However, in the last five years tremendous advances have occurred with the launch of three separate lightning detectors in space (OTD, LIS and FORTE) (Christian and Latham, 1998; Jacobson et al., 1999). We now know that the vast majority of lightning activity is located over the continental regions of the globe, with little lightning ever being found over the oceans. The reason for this is still debated; however, it is related to the differences in the microphysics of oceanic and continental deep convection (Price and Rind, 1992). Observations have shown significant differences in the updraft intensities in storms, with the oceanic storms rarely having updraft intensities greater than 10 m/s. The intensity of the updrafts is very important for the electrification processes, due to the vertical transport of supercooled droplets and graupel particles (Williams et al., 1992).

As a result of the global distribution of lightning, there are three main centres of lightning activity over the three tropical continental landmasses (South America, Africa, and South East Asia/Maritime Continent). In addition to the tropical lightning, extratropical lightning activity plays a major role in the summer season in the northern hemisphere, resulting in the global lightning activity having a maximum in June–August. Since the daily lightning activity in the tropics maximizes late in the local afternoon (16–18 local time), the combination of spatial and temporal activity produces the well-defined diurnal cycle in measurements of the global electric circuit (the 'Carnegie curve').

Whipple (1929) showed the agreement between the diurnal cycle of the global circuit and the diurnal cycle of global thunderstorm activity. Markson (1986) showed that individual measurements of the ionospheric potential agree well with the 'Carnegie curve', confirming that lightning plays a major role in the global electric circuit. Clayton and Polk

(1977) also showed good agreement between the AC component of the global circuit (Schumann resonances, see below) and global lightning activity. All these studies showed that the global electric circuit has a maximum at approximately 1800 UT, and a minimum at 0300 UT (Price, 1993).

As mentioned above, global lightning activity has a seasonal cycle with a maximum in the northern hemisphere summer. This annual cycle is also observed in the various measures of the global electric circuit. Hence, monitoring the global electric circuit, either via the DC components (ionospheric potential, fair-weather current) or via the AC component (Schumann resonances) provides a good proxy for global lightning activity.

5.2. *Sprites*

In the last decade, a completely new discovery has been made in the field of atmospheric electricity. Optical flashes have been observed high above thunderstorms, reaching altitudes of up to 100 km. These luminous transient events lasting from 1 to 100 ms have been named elves, sprites and blue jets. In the last few years the research in this area has increased dramatically (see Sentman and Wescott, 1996; Rodger, 1999, and a Special Issue of JASTP (May/June 1998)). It is now believed that all three phenomena are independent of each other, although sometimes they may occur simultaneously. Most of the advances in this field have occurred as the result of dedicated field experiments in the United States. During the summer months, mesoscale convective systems develop over the United States, which provide a natural laboratory for studying sprites. Observations have been taken on the ground (Lyons, 1996), from aircraft (Sentman and Wescott, 1993), and from high-altitude balloons (Bering et al., 1999). It appears that elves occur with all lightning discharges. The electromagnetic pulse (emp) produced by the lightning propagates up into the stratosphere and mesosphere, producing large electric fields that result in a ring of light at the base of the ionosphere (Cho and Rycroft, 1998), similar to the airglow phenomenon. This ring expands outwards as the emp propagates away from the lightning source in the storm below. The elves last only a few milliseconds, and they can only be seen with very sensitive low-light-level cameras. The propagation of elves outward has been observed using high-speed photometers (Inan et al., 1997).

Sprites are the more spectacular events, and are caused by only a small fraction of the lightning discharges within the storm below. We now know that sprites occur simultaneously with positive cloud-to-ground lightning (Boccippio et al., 1995), although recently there has been some evidence of negative cloud-to-ground flashes producing sprites (Barrington-Leigh et al., 1999). Sprites are red in colour as a result of the excitation of the N_2^+ line. The lifetime of sprites is much longer than that of elves, up to 50 milliseconds, and they occupy volumes greater than 1000 km^3. The removal of charge from the cloud by the positive discharge is thought to result in the stressing of the upper atmosphere. The screening layer around the anvil of the cloud immediately after the ground discharge acts as the charged plate of a horizontal capacitor, producing large fields above the storm in the mesosphere. The enhanced field accelerates electrons in the low-density mesosphere, colliding with N_2 molecules, resulting in the emission of red light. The relaxation time of the screening layer is some tens of milliseconds, the time scale of the sprites.

Do sprites influence the global electric circuit? This is still an unanswered question. Although sprites occur in the upward branch of the global circuit above thunderstorms, hence influencing the conductivity of the upper atmosphere (the resistor R_1 in Fig. 5), they occur much less frequently than regular lightning. Observations indicate approximately 1 sprite for every 200 lightning discharges. Therefore, due to their low occurrence rate they may not pay a major role in the global electric circuit. This is a topic of future research.

5.3. *Schumann resonances*

A paper in this issue (Barr et al., 2000, this issue) describes in detail the history and development of Schumann resonances (SR). The SR are produced by electromagnetic radiation from lightning being trapped in the Earth-ionosphere waveguide. At extremely low frequencies (ELF), very little attenuation occurs, allowing these radio waves to propagate a few times around the globe before dissipating. Constructive interference produces standing resonant waves at $8, 14, 20, 26, \dots$ Hz, where the 8 Hz mode represents a wave with wavelength equal to the circumference of the Earth (40,000 km); see also Rycroft (1965) and Fuellekrug and Fraser-Smith (1996). Hence, similar to the DC fair-weather global circuit measurements, the SR can also be monitored from a single position on the Earth's surface.

Research on SR is twofold. The background SR signal intensities are well correlated with global lightning activity (Heckman et al., 1998); hence, the SR are used for studying the global variability of lightning activity (Satori, 1996; Nickolaenko et al., 1998). On the other hand, the transient SR signals have been shown to be well correlated with sprite activity (Boccippio et al., 1995; Cummer et al., 1998). Therefore, we are also able to use the SR measurements to study sprites on a global scale (see Fig. 6).

Unlike the DC circuit that is influenced by changes in the conductivity of the atmosphere, the SR are dependent only on global lightning activity. Hence, the AC component of the global circuit is better correlated with global lightning activity than is the DC component.

6. Climate change and the global electric circuit

In recent years a new and important application of the global electric circuit has become evident. The global

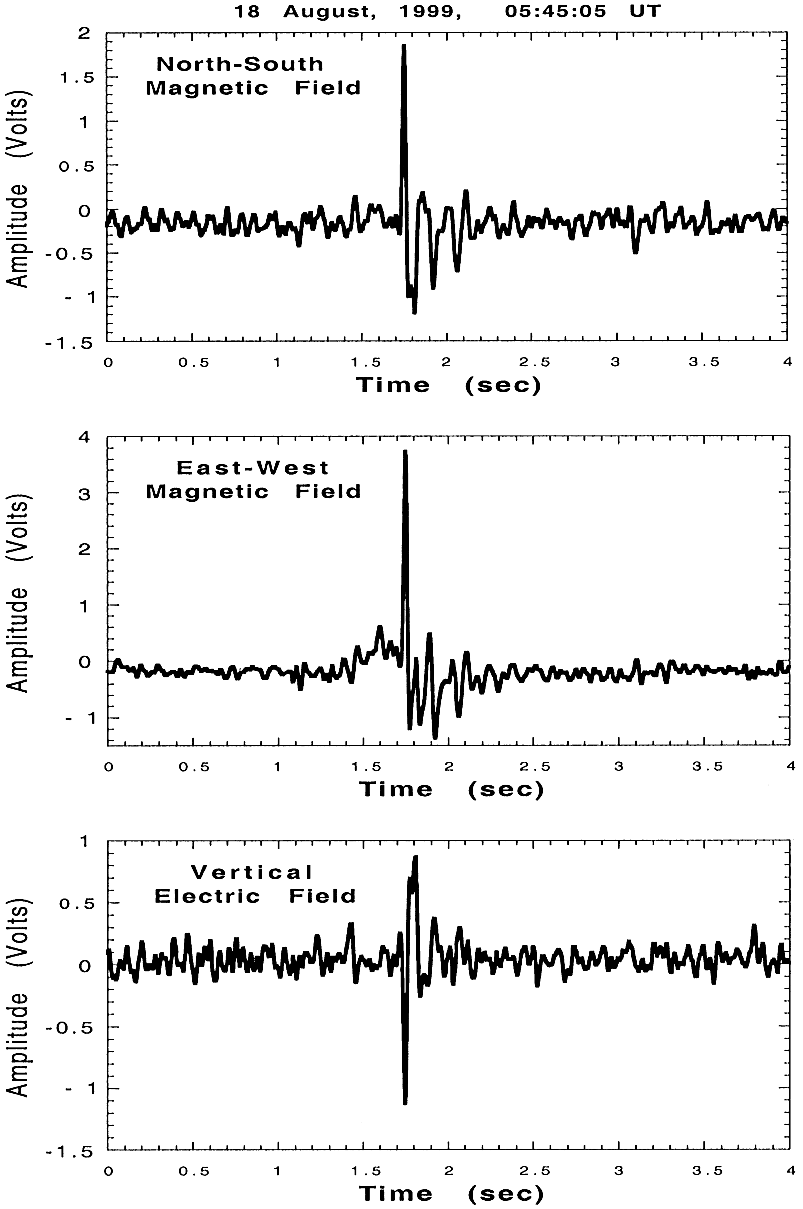

Fig. 6. The ELF radio signals observed in Israel associated with a sprite generated in the United States.

circuit is becoming an important tool in studying the Earth's climate, and climate change. Price and Rind (1990) first proposed the possibility that changes in the Earth's climate could result in more lightning activity around the planet. Since then global lightning activity and the global electric circuit have been shown to be closely related to various important climate parameters.

Williams (1992) showed the close relationship between tropical surface temperatures and the monthly variability of the SR measured in Rhode Island, USA. A similar study was conducted by Fuellekrug and Fraser-Smith (1997), showing a connection between ELF observations in Antarctica and Greenland and global surface temperatures. Price (1993) showed a good agreement between the diurnal surface temperature changes and the diurnal variability of the global electric circuit ('Carnegie curve'). This study also showed a strong link between the frequency/intensity of global deep convection and global surface temperatures. Markson and Price (1999) used direct measurements of the ionospheric potential to further demonstrate the positive correlations between global and tropical surface temperatures and the ionospheric potential. Recently, Reeve and Toumi (1999) used new satellite lightning observations to show the agreement between globally observed lightning activity and global temperatures. Finally, a recent study by Price (2000) has extended the above connections to additional climatic parameters such as upper tropospheric water vapour; the variability of upper tropospheric water vapour is closely linked to the variability of global lightning activity, measured via the SR.

Therefore, by monitoring the global electric circuit, we may be able to study, in a cheap and consistent way, the variability of global lightning activity, which is closely related to surface temperatures, tropical deep convection, rainfall, upper tropospheric water vapour, and other important parameters that affect the global climate system. The advantage of these measurements is that they can be made continuously, for many years, unlike satellite sensors that generally have a relatively short lifetime of only a few years, or even less.

7. Potential applications and recommended atmospheric electricity research

An increased interest in understanding the Earth's electrical environment has resulted from recent advances in different disciplines, along with the recognition that many of man's modern technological systems can be adversely affected by this environment. The cornerstone of our understanding of the Earth's electrical environment and the global electrical circuit is an integration of measurements, theory, and modelling. There should be a concerted effort of coordinated measurement compaigns, supported by critical laboratory experiments, theory, and numerical modelling of processes, to improve our understanding of the Earth's electrical environment.

It is also an opportunity to further investigate relationships/correlations between atmospheric aerosols and electrical parameters, with the advent of more widely available aerosol measurement capabilities. A proper understanding of the impact of aerosols on climate rests both on quality-assessed measurements, and on a predictive modelling capability which enhances our ability to understand complex and nonlinear interactions between aerosols and atmospheric electric parameters. An interesting and novel approach in linking atmospheric electricity parameters and lightning activity to the global electric circuit and to global warming provides the basis for other crucial modelling initiatives.

The global circuit of atmospheric electricity is influenced by meteorological processes. These influences are incorporated in the current that flows in the global circuit. As the electric conductivity of the troposphere and the stratosphere is so much lower than that of the ground and that of the ionosphere, the potential difference between these two highly conducting layers indicates the strength of the global circuit current and its variations with time. In measuring the electric field or the air-Earth current density at any one station, we may obtain information about those meteorological processes that, world-wide, influence the global circuit current. At the same time, the data obtained by measuring the electric field and/or the air-Earth current density are also influenced by local events at and above the measuring stations. These events may be generators for local electric circuits or may cause variations of resistances in the circuit. Therefore, we must basically consider that in the data thus obtained we are witnessing influences both from processes that occur over the entire globe at the same time, as well as from purely local events. If the scientists in atmospheric electricity had the chance to separate these contributions, we might have a tool of significance for global change problems.

The ionospheric potential, electric field and air-Earth current density measurements in the PBL with periods shorter than a few hours are usually attributed entirely to local sources, primarily turbulence and pollution. Recent advances that have been made in independent research areas examine the interrelations between them, and project how new knowledge could be applied for the benefit of mankind. They also indicate needs for new research and for the types of coordinated efforts that will provide significant new advances in basic understanding and in applications over the next few decades. They emphasize a need to consider the interactions between various atmospheric, ionospheric, and telluric current systems to achieve an overall understanding of global electrical phenomena.

Evaluating the present situation from this vantage point, we can perceive three main approaches from atmospheric electricity to the global change monitoring effort:

1. Measure local parameters at many places and attempt meaningful integrations for the results over areas of global importance, optimally for the whole globe.
2. Measure local parameters and follow local processes at locations where they may be representative for larger areas; the expectation is that this will be the case for the oceans far from their shores.
3. Find global contributions to local measurements, and derive global information from a rather small number of local stations.

The global detection of lightning is necessary to determine the global flashing rate and how this rate relates to other parameters in the global circuit. NASA has developed new optimal sensors that could be used to detect and locate lightning in the daytime or at night, and with continuous coverage by using satellites in geosynchronous orbits. These sensors are capable of measuring the spatial and temporal distribution of lightning over extended periods with good spatial resolution; they offer significant new opportunities for research and for many applications.

There are ample reasons for interest in global-scale atmospheric electrical phenomena. For example, valuable information about the distribution and temporal variability of horizontal potential differences in the ionosphere could be provided by monitoring the ionospheric potential simultaneously in different locations. Furthermore, the widely accepted relationship between global thunderstorm activity and ionospheric potential has yet to be verified on anything but the crudest statistical basis. From the present perspective, finally, a detailed knowledge of the forcing from the global circuit would be useful in evaluating the electrical response of the PBL.

Seen from our present state of knowledge and our present priorities, the following atmospheric electricity elements should be investigated. Are they changing over time? If so, how and why?

- Thunderstorm nature, frequency, and geographic distribution; assess secular changes in the number of thunderstorms and/or of lightning.
- Ionosphere-Earth potential difference; assess its changes by direct or indirect measurements of air-Earth current density at the ground or in the air.
- Atmospheric electrical conductivity and its changes at a selection of typical stations, with various local atmospheric and geographic conditions and of types of anthropogenic influences.

In a recently published book, the Board of Atmospheric Sciences and Climate of the US National Research Council (1998) has presented a few Recommended Atmospheric Electricity Research Topics. These are to

- Investigate the possibility that the global electrical circuit and global and regional lightning frequency might be an indicator of climate change.
- Determine mechanisms responsible for charge generation and separation in clouds to understand cloud formation mechanisms and elucidate the fundamental physics of lightning.
- Determine the nature and sources of middle-atmospheric discharges to (1) increase knowledge of these recently discovered phenomena and their possible association with severe weather, and (2) explore their effects on radio propagation and atmospheric chemistry.
- Quantify the production of oxides of nitrogen (NO_x) by lightning to better understand upper-troposphere ozone production or loss.

The European Science Foundation has recently established a Network on "Space weather and the Earth's weather electrodynamic and charged particle effects on the stratosphere and troposphere". The overall aim of that interdisciplinary study, now named Space Processes and Electrical Changes Influencing Atmospheric Layers (SPECIAL), is to

- review and investigate such subjects,
- generate and test some hypotheses on the effects of energetic charged particles on the atmosphere, and
- consider their effects on weather and climate (also see Feynman and Ruzmaikin, 1999).

Thus, it is evident that the "old" subject of atmospheric electricity is very much "alive and kicking" today. Indeed, in the next decade or so, it may experience a renaissance.

8. Conclusions and discussions

The study of atmospheric electricity and the global electric circuit has advanced dramatically in the past 50 years. Our knowledge of the global electric circuit modulated by solar effects has improved, although there are generally more questions than answers in this field of atmospheric electricity. Regarding aerosols and atmospheric ions, advances have been made in studying air pollution using atmospheric electricity, and we have a better understanding of how the conductivity of the atmosphere is influenced by aerosols, and how this impacts our measurements of the fair-weather global circuit.

Perhaps the largest advances have been made in the areas of lightning and thunderstorm research, as related to the global circuit. We now have satellites looking down on the Earth continuously, supplying information on the temporal and spatial variability of lightning and thunderstorms. New discoveries have been made in the field of sprites, elves and blue jets, which may have a direct impact on the global circuit and how we model the global circuit.

Finally, the global atmospheric electric circuit is now starting to be recognised by some climate researchers as a useful tool to study and monitor the Earth's changing climate. The global electric circuit is the only climate-related parameter that can be measured at a single location on the Earth's surface, and yet supply global information. This unique quality should encourage additional research in this field.

Although there have been dramatic advances in the field of sprites, lightning, and even the Schumann resonances over the last decade, there is a need for an increased understanding of the solar-terrestrial connection. How do changes in solar particles and cosmic radiation, and also the solar wind, influence the Earth's climate? How strong is this connection? Is it mainly a high-latitude connection, or can tropical thunderstorms be affected by changes in the solar wind flux? What about variations over the solar cycle? These and many more questions need to be addressed in future research.

Our need to assess environmental impacts on human kind's technological systems requires a better understanding of electrical processes in the Earth's atmosphere than we now possess. Further research is needed to understand better the natural electrical environment and its variability and to predict its future evolution.

[57] **ABSTRACT**

A fire selector system for selecting between automatic and semi-automatic operation of a gun is provided. The system is mountable on a reciprocating slide of the gun and into operative relationship with the trigger bar of the gun. A member of the selector system is movable between forward and rearward longitudinal positions. The forward longitudinal position allows the member to assume an activating longitudinal position for automatic operation of the gun. The rearward longitudinal position prevents the member from assuming its activating longitudinal position, thereby effecting semi-automatic operation of the gun. The member repetitively contacts a contact area of the trigger bar as it reciprocates with a reciprocating slide of the gun during automatic operation. Further, the device is easily installed and removed from the reciprocating slide depending on user requirements.

FIG. 5c

FIRE SELECTOR SYSTEM FOR SELECTING BETWEEN AUTOMATIC AND SEMI-AUTOMATIC OPERATION OF A GUN

TECHNICAL FIELD

This invention relates to semi-automatic and automatic firearms. More particularly, this invention is a fire selector system for selectively converting a firearm between semi-automatic and automatic operation.

BACKGROUND OF THE INVENTION

Many firearms are sold in configurations which provide semi-automatic operation or automatic operation. However, it is often desirable to convert an existing semi-automatic firearm to an automatic firearm, without significant modification thereof.

Having made an initial investment in a semi-automatic firearm, many users are inclined not to make an additional, potentially equal investment in a related firearm which provides automatic operation.

Various mechanisms have been proposed in the prior art for effecting selection between semi-automatic and automatic operation. For example, U.S. Pat. No. 3,012,479 to L. E. Ruffell discloses an abutment opposite a recess in a sear, and movable between three positions for safe, semi-automatic, and automatic operation. However, this device does not appear to convert an existing semi-automatic gun to automatic operation. U.S. Pat. No. 2,572,872 to S. J. Ketterer discloses an attachment for converting a semi-automatic rifle to full automatic, but which is dependent on pivoting motion of a lever, triggered by forward movement of a bolt. An arm of the lever thereby rotates a sear into a hammer releasing position to effect automatic operation. This pivoting action of the retrofitted attachment requires significant, independent movement of the attachment itself during automatic operation, which is undesirable as it may lead to failures, mis-fires, etc. Further, cuts to the stock of the rifle are necessary to install the attachment.

Thus, what is required is a simple device for converting a semi-automatic firearm into an automatic firearm. It is preferable that such a device have few moving parts, be easily installed and removed from the existing semi-automatic firearm, operate in a simple manner, and be inexpensive.

SUMMARY OF THE INVENTION

The shortcomings of the prior art are overcome by the present invention, which in one aspect is a device for converting a semi-automatic gun into an automatic gun. The gun has a trigger bar, a reciprocating slide, and a longitudinal firing mechanism. The trigger bar is normally mounted below the firing mechanism and is movable into a first position in which the trigger bar engages the firing mechanism and prevents forward motion of the firing mechanism following trigger activation. Semi-automatic operation is thus effected by this engagement. The converting device includes a member mountable on the reciprocating slide of the gun and into operative relationship with the trigger bar of the gun. The member is movable into an activating longitudinal position in which contact between the member and a contact area of the trigger bar occurs to urge the trigger bar away from its first position following trigger activation. Automatic operation of the gun is thus effected by this contact.

The member may be reciprocatable by a user between forward and rearward longitudinal positions. The forward longitudinal position allows the member to assume its activating longitudinal position for automatic operation of the gun. The rearward longitudinal position prevents the member from assuming its activating longitudinal position and thereby allows the trigger bar to assume and retain its first position following trigger activation thus effecting semi-automatic operation.

The device may include a switch for longitudinally moving the member between its forward and rearward longitudinal positions.

The device reciprocates with the reciprocating slide upon its mounting thereon, and, when in its forward longitudinal position, can assume its activating longitudinal position and repetitively contact the contact area of the trigger bar during its reciprocation with the reciprocating slide. The member does not assume its activating longitudinal position and is thus isolated from the contact area of the trigger bar during its reciprocation when the member is in its rearward longitudinal position.

The member may include a tapered tip for contacting the contact area of the trigger bar, the tapered tip gradually urging the trigger bar away from its first position as the member is moved into its activating longitudinal position.

As set forth in greater detail hereinbelow, the fire selector system of the present invention can be easily installed and removed from an existing semi-automatic firearm, thus providing the option of a convertible gun or a non-convertible gun. Further, the fire selector system has very few moving parts, operates in a simple manner and is relatively inexpensive to fabricate.

BRIEF DESCRIPTION OF DRAWINGS

The subject matter which is regarded as the invention is particularly pointed out and distinctly claimed in the concluding portion of the specification. The invention, however, both as to organization and method of practice, together with further objects and advantages thereof, may best be understood by reference to the following detailed description of the preferred embodiment(s) and the accompanying drawings in which:

FIG. 1*a* depicts a partial cross-section of an exemplary gun having the fire selector system of the present invention mounted therein, the gun being cocked and ready to fire a single round, the fire selector system being set for semi-automatic operation;

FIG. 1*b* depicts a position of the components of the gun of FIG. 1*a* at a point during a trigger activation;

FIG. 1*c* depicts the gun having the fire selector system therein, the fire selector system being set for automatic operation, the components shown at a point following trigger activation and during forward movement of the reciprocating slide;

FIG. 1*d* depicts the moment of firing of the gun of FIG. 1*c*;

FIG. 2 is a perspective view of the trigger bar and fire selector systems of FIGS. 1*a*–*d*, and further illustrates the positional relationship therebetween;

FIGS. 3*a*–*b* are various views of the fire selector system of the present invention in its extended (automatic) and retracted (semi-automatic) settings, respectively;

FIGS. 4*a*–*b* depict an alternate embodiment of the fire selector system in its extended and retracted positions, respectively; and

FIGS. 5*a*–*c* are cross-sectional views depicting additional detail of the fire selector system of FIGS. 1–3.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT(S)

With reference to FIGS. 1*a–d*, depicted therein is an exemplary pistol **10** having a fire selector system **100** installed thereon, according to the principles of the present invention. FIGS. 1*a–b* depict the fire selector system in its setting for semi-automatic operation. FIGS. 1*c–d* depict the fire selector system in its setting for automatic operation.

As shown in FIG. 1*a*, the components of the gun **10** relevant to the instant invention are as follows. Trigger **20**, shown in its unactivated position, is hingedly connected to a trigger bar **18**. A wing **28** of trigger bar **18** is engaging a leg **16** of firing pin **14** (or mechanism). Following backward motion of the trigger, or trigger activation, trigger bar **18** moves rearward and an inclined end **24** thereof contacts an inclined control surface **26** (perpendicular to the page) of a connector **22**. As end **24** reaches inclined control surface **26**, the trigger bar is pushed downward such that nose **16** is released and, urged by spring **32**, firing pin tip **34** will move forward, contact bullet **30**, and discharge the same.

Pursuant to the principles of the present invention, a fire selector system **100** is provided on the rear of the slide **12**. The system **100** has a housing **106** adapted for mounting on the slide, a switch **104** and a disconnector member **102**. Disconnector **102** is movable into either a forward or rearward longitudinal position using switch **104**. Disconnector **102** in FIGS. 1*a–b* is shown in its rearward longitudinal position, for semi-automatic operation. In this position, no interaction will take place between the fire selector system and the trigger bar of the gun. Therefore, as discussed above, normal semi-automatic operation will occur based on the interaction between trigger bar end **24** and control surface **26** upon activation of the trigger.

Such trigger activation is shown in FIG. 1*b*, wherein the components of the gun are shown at a moment during trigger activation. Wing **28** has pulled leg **16** backward to a point where the end **24** of trigger bar **18** (now obscured by connector **22**) is beginning to contact inclined control surface **26**. Upon further trigger pull, the control surface **26** will guide trigger bar **18** downward, thereby releasing leg **16** and bolt **14** and firing the gun. As discussed above, the disconnector **102** of fire selector system **100** is generally out of engagement with any of these firing components of the gun during semi-automatic operation. Thus, the gun functions in its normal, semi-automatic operation with disconnector **102** in its rearward longitudinal position. Discharge of the bullet and the subsequent backward motion of the slide **12**, and release of the trigger, will effect a re-engagement of wing **28** with leg **16**, in preparation for another trigger activation.

FIGS. 1*c–d* depict automatic operation of the gun, wherein the disconnector **102** of the fire selector system **100** is shown in its forward longitudinal position (i.e., moved a distance **101**). FIG. 1*c* depicts forward motion of the slide following recoil from a previous trigger activation. Inclined surface **116** of the forward tip of the disconnector **102** has been moved a sufficient distance **101** forward such that contact and downward motion of the trigger bar occurs. This contact occurs at a point **19** about 1 or 2 millimeters before the slide **12** reaches its normal forward position. The firing pin **14** is thus released at this point in the reciprocation of the slide and another shot is fired without a trigger activation. Control surface **116** of the disconnector **102** contacts the trigger bar **18** to effect this firing. FIG. 1*d* depicts the moment of firing at which time the control surface **116** of the disconnector **102** has made contact approximately at a point or contact area **40** of the trigger bar. The longitudinal position at which the disconnector begins to engage the trigger bar is referred to herein as the activating longitudinal position.

As long as the trigger is pulled, and ammunition is provided in the clip, the disconnector will repetitively disengage the firing pin by repetitively engaging the trigger bar and repetitive firing will result as the selector system reciprocates with the slide.

FIG. 2 depicts, in perspective form, the relevant components effecting automatic operation including trigger **20**, trigger bar **18** and selector system **100**. The inclined control surface **116** of disconnector **102** of the selector system **100** is designed to effect contact at about contact area **40** of trigger bar **18**, and gradually urge the trigger bar **18** downward as the disconnector moves forward.

FIG. 3*a* includes side, top and rear views of the fire selector system of the present invention, with the disconnector **102** in its extended (automatic) setting. As discussed above, the components of this system **100** include a disconnector **102**, housing **106** and a cylindrical switch **104** running laterally through the housing. A pin **108** can be provided to hold the disconnector **102** in housing **106**. Further, the housing **106** may have a flange **112** formed thereon to effect simple installation and removal of this selector system from the gun. FIG. 3*b* depicts the same views of the selector system with the disconnector in its retracted position, using the opposite switch setting. FIGS. 3*a* and 3*b* clearly show that a first switch position effects extension of the disconnector **102** thus effecting automatic operation, and a second switch position effects retraction of the disconnector **102** thus effecting semi-automatic operation.

FIG. 4*a* includes side, top and rear views of an alternate embodiment **200** of a selector system pursuant to the principles of the present invention, with the disconnector in its extended (automatic) setting. Disconnector **202**, housing **206** and pin **208** are similarly provided, however, a thumb switch **204** is provided in this embodiment rather than the cylindrical switch running laterally through the housing set forth in FIG. 3. FIG. 4*b* depicts the same views of the alternate embodiment **200** of the fire selector system with the disconnector in its retracted (semi-automatic) setting.

FIG. 5*a* is a sectional, side view of the fire selector system of FIGS. 3*a–b*, illustrating additional detail of the system. A spring **110** is shown therein which operates to urge the disconnector **102** into a rearward position. Pin **108** is shown positioned through a via **118** of the member **102**. The pin is shown in front of the via indicating that the disconnector **102** is in its retracted longitudinal position. An inclined surface **119** of the disconnector **102** facilitates movement of the disconnector **102** between its retracted and extended longitudinal positions, as illustrated in the sectional, top views of FIGS. 5*b–c*, which also show a cross-section of the laterally positioned switch **104**. Switch **104** includes a recess **114** into which disconnector **102** is urged by spring **110** in its retracted position. Further, a small ridge **117** is provided which, as shown in FIG. 5*c*, holds disconnector **102** in its extended longitudinal position. The inclined surface **119** of the disconnector facilitates movement into the extended position, and the inclined surfaces of ridge **117** similarly facilitate movement from the extended position into the retracted position.

Various dimensions of the fire selector system of FIGS. 5*a–c* are set forth in the table below.

120	54°
122	21.95 mm
124	4.65 mm
126	2 mm
128	2.45 mm
130	2.06 mm
132	4.81 mm
134	14.7 mm

An exemplary embodiment of the fire selector system is fabricated using glass filled reinforced polymer for the switch and housing, hardened steel for the disconnector and spring, and carbon steel for the pin.

The above-described selector system therefore has few moving parts, and further is composed of relatively inexpensive parts.

Using the above-described dimensions for the housing and disconnector, a fire selector system is provided to select between semi-automatic and automatic operation of a Glock pistol of the type described in U.S. Pat. No. 4,825,744, hereby incorporated herein by reference in its entirety. The fire selector system of the present invention can be adapted to replace a slide cover plate of that pistol at the rear of the slide, and it can thus be easily installed and removed from the pistol. In its installed position, the fire selector system provides the user with a choice between semi-automatic and automatic operation; and upon its removal, the gun operates in its normal semi-automatic mode.

While the invention has been described in detail herein in accordance with certain preferred embodiments thereof, many modifications and changes therein may be affected by those skilled in the art. Accordingly, it is intended by the following claims to cover all such modifications and changes as fall within the true spirit and scope of the invention.

What is claimed is:

1. A device for converting a semi-automatic gun into an automatic gun, the gun having a trigger bar, a reciprocating slide, and a longitudinal firing mechanism, the trigger bar mounted below the firing mechanism and movable into a first position in which the trigger bar engages the firing mechanism and prevents forward motion of the firing mechanism following trigger activation, thereby effecting semi-automatic operation, the device comprising:

a member mountable on the reciprocating slide of the gun and in operative relationship with the trigger bar of the gun, the member movable into an activating longitudinal position in which contact between the member and a contact area of the trigger bar occurs to urge the trigger bar away from its first position following trigger activation thereby effecting automatic operation of the gun, wherein the member is reciprocatable between forward and rearward longitudinal positions, the forward longitudinal position allowing the member to assume its activating longitudinal position for said automatic operation of the gun, the rearward longitudinal position preventing the member from assuming its activating longitudinal position, thereby allowing the trigger bar to assume and retain its first position following trigger activation to effect said semi-automatic operation of the gun;

and wherein the device further comprises a user switch coupled for longitudinally moving the member, the user switch having a first position corresponding to the forward longitudinal position of the member and a second position corresponding to the rearward longitudinal position of the member.

2. The device of claim **1**, further comprising a housing in which the member and the user switch are mounted, the housing adapted to be mountable on a rearward portion of the reciprocating slide of the gun with said member extending forward into the reciprocating slide and into the operative relationship with the trigger bar of the gun upon mounting of the housing on the rearward portion of the reciprocating slide.

3. The device of claim **2**, wherein the device reciprocates with the reciprocating slide upon its mounting thereon, the member assuming its activating longitudinal position and repetitively contacting the contact area of the trigger bar during its reciprocation with the reciprocating slide when the member is moved into its forward longitudinal position, the member not assuming its activating longitudinal position and being isolated from the contact area of the trigger bar during its reciprocation with the reciprocating slide when the member is moved into its rearward longitudinal position.

4. The device of claim **1**, wherein the user switch is elongate and runs laterally through the housing, and wherein the device comprises a spring for urging a rearward end of the member against a side of the user switch, the side of the user switch having a recess, such that:

in a first lateral switch position comprising said first position, the rearward end of the member is positioned outside of the recess and the member thereby assumes its forward longitudinal position, and

in a second lateral switch position comprising said second position, the rearward end of the member is urged into the recess and the member thereby assumes its rearward longitudinal position.

5. A device, mountable on a rearward portion of a semi-automatic gun, for selectively converting the gun between semi-automatic and automatic operation, the device comprising:

a housing adapted to be mountable on the rearward portion of the gun; and

a member extending from said housing and into the gun upon mounting of the device on the gun, the member movable between an extended longitudinal position and a retracted longitudinal position, wherein

in the extended longitudinal position a forward end of the member engages a trigger bar of the gun and urges the trigger bar out of engagement with a firing mechanism of the gun following trigger activation thereby effecting said automatic operation, and

in the retracted longitudinal position, the member is disengaged from the trigger bar of the gun following trigger activation, thereby effecting said semi-automatic operation;

and wherein the device further comprises a switch for moving the member between its extended and retracted longitudinal positions.

6. The device of claim **5**, wherein the forward end of the member is tapered, the tapered forward end gradually urging the trigger bar out of engagement with the firing mechanism when the member is in its extended longitudinal position.

7. A gun having a device therein for facilitating selection between semi-automatic and automatic operation of the gun, the gun having a trigger bar and a firing mechanism, the trigger bar being disposed below the firing mechanism and movable into an upper position in which the trigger bar engages the firing mechanism and prevents forward motion of the firing mechanism following trigger activation to effect said semi-automatic operation, the device comprising:

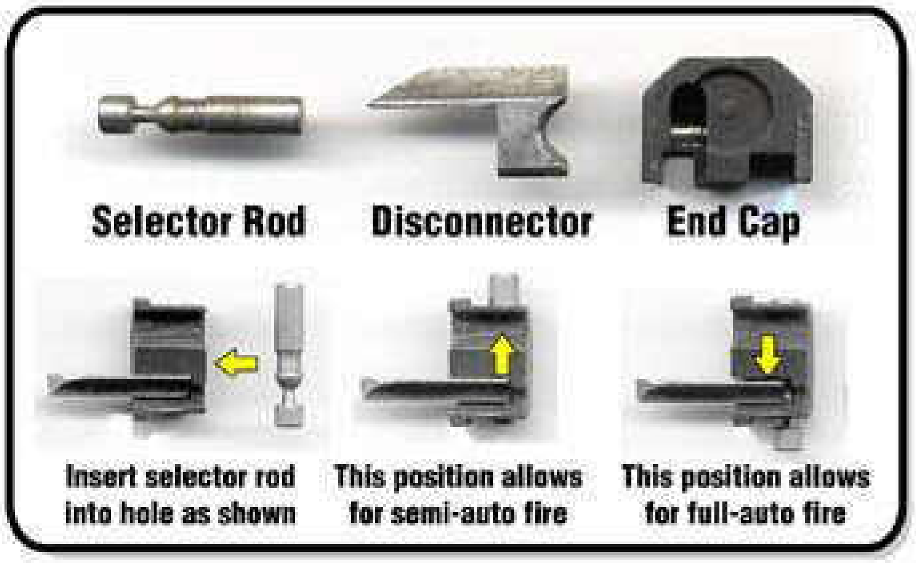
a member for placement in operative relationship with the trigger bar of the gun and moveable by a user between a forward and rearward longitudinal position, the rearward longitudinal position of the member allowing the trigger bar to assume its upper position following trigger activation thereby effecting said semi-automatic operation by allowing engagement between the trigger bar and the firing mechanism, the forward longitudinal position of the member effecting contact between the device and the trigger bar and urging the trigger bar

away from its upper position following trigger activation thereby effecting said automatic operation, wherein the device includes a user switch for longitudinally moving the member, the user switch having a first position corresponding to the forward longitudinal position of the member and a second position corresponding to the rearward longitudinal position of the member.

* * * * *

INSTALLATION PROCEDURE FOR THE GLOCK 9MM PISTOLS

All NFA Rules and Regulations Apply!



Selector Rod
Disconnector
End Cap
Insert selector rod into hole as shown
This position allows for semi-auto fire
This position allows for full-auto fire

Step (1) Assembly Of The Unit:

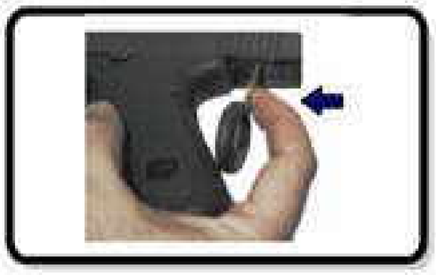
Your Glock device consists of three parts; Selector Rod, Disconnector, and an End Cap. These three items will replace your existing plastic "End Cap" located on the back most part of your Glock 9mm pistol. These pictures show the assembled unit along with the two positions for the "Selector Rod".

Please note that when the "Selector Rod" is set for full-auto fire, you are still able to control the amount of fire from the pistol through trigger pul.. A short, quick trigger pull will release a small burst while a lengthy pull will release as many as your Glock 9mm magazine can hold.

Proper care should be given to all parts of the device assembly as well as observing all BATF laws and regulations relevant to this device.

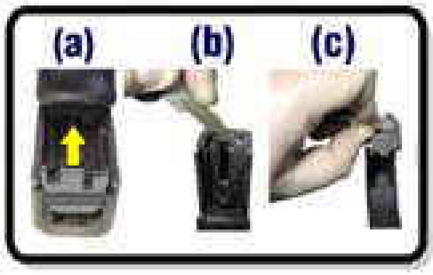
Step (2) Preparing For Installation:

Verify that you are working with a UNLOADED weapon by inspecting the chamber for loose rounds and any magazines that may be used in the process of installing the Glock device. Pull back the slide of your Glock with an EMPTY magazine installed. This places the weapon in the "Out of Ammo" mode. This will allow you to comfortably install the Glock device without disassembly of the weapon. Have a sturdy key or screwdriver handy for installation. Be careful not to damage any surrounding parts and above all, do not force the parts!.



Step (3) Preparing For Installation:

Use you sturdy car key or a flathead screw driver between the firing pin notch and the firing pin jacket as shown in the illustration to the left. Push the key or screwdriver towards the front of the gun. This will allow you to remove the existing end cap



Step (4) Preparing For Installation:

While you are holding back the firing pin you can now easily remove the existing end cap as shown in illustration (a). After you have successfully removed the existing end cap, again use the key or screwdriver to push the firing pin jacket from the rear to allow your fully assembled Glock device to slip over and into the empty end cap slot as shown in illustration (b). Use the key or screwdriver again to push back the extractor plunger to allow the fully assembled device to completely slide into the end cap slot as shown in illustration (c).

Step (5) Preparing For Test Firing:

Pull and release the slide several times to allow the device to create a small channel for the disconnector on the frame. Your Glock pistol is now ready to test fire. Please see the illustrations above for setting the "Selector Rod" to allow for full-auto or semi-auto fire.

Troubleshooting:

If the pistol does not close or closes improperly simply disassemble the device from the weapon and replace with the standard "End Cap". If the slide now closes, the problem is with the disconnector. There are two possible reasons for this:

(1) The disconnector's gap has not formed. (Verify that there is a gap formed by the disconnector. If not, repeat step (5) after reassembly.

(2) The curved part of the disconnector does not allow the trigger to complete a cycle. There are two methods to correct this:

   (a) With a Dremel tool and a sanding stone you could enhance the disconnector's shape. (caution not to over-sand).

   (b) With a Dremel tool and a sanding cylinder you can smooth out the trigger bar's little notch (you should disassemble the pistol before doing this).

Installing the Device without selector bar or disconnector (and further troubleshooting):

If you wish to install the device without the selector rod and the disconnector you may still have difficulty with a non-closing slide. Try the following:

(1) Using sand paper, sand the left side (square protuberance on the top) allowing the device to enter with the slide over the frame

(2) Use a small file to file the device a small amount in the recesses opposite to the disconnector.

(57) **ABSTRACT**

A pyramid electric generator for harvesting the vibrational energies of Earth's atomic oscillators according to the present invention comprises: (1) an antenna/waveguide that is geometrically optimized; (2) a coil wound with an insulated conductor on a nonconductive coil form, the coil being connected at its top lead to the conducting surface of the antenna/waveguide such that the coil is connected near the point at which the electric field contacts the antenna/waveguide, the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency; (3) the bottom lead of the coil is connected to a driver operating in the LF or ELF bands. In another mode of operation, a secondary coil is positioned coaxially within the first coil acting as a resonant step-up transformer winding. The generator resonantly couples into specific frequencies of Earth's atomic oscillators and extracts electric energy thereof.

PYRAMID ELECTRIC GENERATOR

CROSS-REFERENCES

[0001] This application is a continuation-in-part of U.S. patent application Ser. No. 12/140,887 by Grandics, entitled "The Pyramid Electric Generator," and filed on Jun. 17, 2008, which was a continuation-in-part of PCT Application Serial No. PCT/U.S.07/69804 by Grandics, entitled "An Electric Power Converter for Extraction of Atmospheric Electrical Energy," designating the United States and filed on May 25, 2007, which in turn claimed priority from U.S. Provisional Application Ser. No. 60/818,360 by Grandics, also entitled "An Electric Power Converter for Extraction of Atmospheric Electrical Energy," and filed on Jul. 3, 2006. The specifications of these three prior applications are incorporated herein in their entirety by this reference.

BACKGROUND OF THE INVENTION

[0002] This invention relates to the generation of electrical power by drawing energy from Earth's electric field. Earth represents a resonant system in which both atmospheric and telluric electrical processes can be harvested. In U.S. Pat. No. 6,974,110, we have provided an apparatus and method for converting the electrostatic potential energy of Earth's atmosphere into usable power. The present invention aims to provide an electric generator that, in addition to tapping atmospheric electric processes, extracts electrical power from the vibrational energy of atomic oscillators by a novel resonant coupling method.

SUMMARY OF THE INVENTION

[0003] An electrical generator according to the present invention provides a new method of tapping Earth's electric energy field.

[0004] One aspect of the present invention is an apparatus for capturing both atmospheric and telluric electric energies, comprising:

[0005] (1) an antenna/waveguide that is geometrically optimized having a conducting surface; and

[0006] (2) a coil wound with an insulated conductor over a non-conductive coil form, the coil being connected to an AC or AC-DC driver at its bottom lead and, by its top lead to the conducting surface of the antenna/waveguide near the point where the electric field contacts the antenna/waveguide, with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency;

wherein the generator absorbs impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms in the coil, representing harvested electrical energy of atomic oscillators and measurable on the leads of the coil.

[0007] Preferably, the antenna/waveguide is of pyramidal shape. When the antenna/waveguide is of pyramidal shape, the apex/primary coil is preferably connected near or at the apex of the antenna/waveguide.

[0008] Another aspect of the invention is an electric generator for harvesting the energies of atomic oscillators comprising:

[0009] (1) an antenna/waveguide that is geometrically optimized having a conducting surface; and

[0010] (2) a primary (apex) coil wound with an insulated conductor over a non-conductive coil form, the coil being connected to an AC or AC-DC driver at its bottom lead and, by its top lead to the conducting surface of the antenna/waveguide near the point where the electric field contacts the antenna/waveguide, and the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency; and

[0011] (3) a secondary coil of smaller diameter than the primary (apex) coil having a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the primary coil and acting as a resonant step-up transformer winding inductively coupled with the primary coil;

wherein the generator absorbs impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveforms in the secondary coil, representing harvested electrical energy of atomic oscillators and measurable on the leads of the secondary coil.

[0012] Yet another aspect of the present invention is an electric generator for harvesting the electric emissions of atomic oscillations comprising an oscillator. In this aspect, the electric generator typically comprises:

[0013] (1) a primary (apex) coil wound with a conductor over a secondary coil, the primary coil being connected electrically at its bottom lead to a driver operating in the LF or ELF bands while connected by its top lead near the point at which the electric field contacts the conductive surface of the antenna/waveguide; and

[0014] (2) a secondary coil of smaller diameter than the primary (apex) coil having a greater number of turns than the primary coil, the secondary coil being positioned coaxially within the first coil and acting as a resonant step-up transformer winding inductively coupled with the primary;

wherein said resonant step-up transformer's output voltage exceeds 500 V_{RMS};

wherein the electric generator attracts impulses from Earth's electric oscillations;

and wherein the attracted energy manifests as high voltage sinusoidal waveforms representing harvested electric energy of atomic oscillations in the secondary coil.

[0015] Another aspect of the present invention is a method of tapping Earth's electric energy field, comprising the steps of:

[0016] (1) positioning an electric generator according to the present invention as described above such that it is exposed to Earth's electric oscillations; and

[0017] (2) generating a sinusoidal voltage signal representing harvested electric energy of atomic oscillators by the operation of the generator.

BRIEF DESCRIPTION OF THE DRAWINGS

[0018] The following invention will be better understood with reference to the specification, appended claims, and accompanying drawings, where:

[0019] FIG. **1** is a graph showing the formation of electric vortices across and around the pyramid.

[0020] FIG. **2** is a graph showing the circuit diagram and measurement points of the pyramid generator.

[0021] FIG. **3** is a graph showing the minimum circuit diagram and relevant measurement points of the pyramid generator.

DETAILED DESCRIPTION OF THE INVENTION

[0022] One aspect of the invention is an apparatus for capturing atmospheric and telluric electric energies, comprising:

[0023] (1) an antenna/waveguide that is geometrically optimized having a conducting surface; and

[0024] (2) a coil wound with an insulated conductor over a non-conductive coil form, the coil being connected to an AC or AC-DC driver at its bottom lead and, by its top lead to the conducting surface of the antenna/waveguide near the point where the electric field contacts the antenna/waveguide, with the antenna/waveguide serving as a quasi-capacitive series element to provide a specific resonant frequency;

wherein the generator absorbs impulses from Earth's electric oscillations; and

wherein the attracted energy manifests as high voltage sinusoidal waveform in the coil, representing harvested electrical energy of atomic oscillators and measurable on the leads of the coil.

[0025] Typically, the electric generator stimulates and attracts the electric emissions of atomic oscillators by the use of high voltage. Typically, the antenna/waveguide is designed based on functions of phi and/or pi.

[0026] In one alternative, the antenna/waveguide is placed on an insulated base.

[0027] Typically, the antenna/waveguide is at a high voltage during the operation of the generator. Typically, the antenna/waveguide voltage is measured by using an E-field antenna.

[0028] The antenna/waveguide can be connected to an oscillator. The oscillator can be a resonant step-up transformer.

[0029] Preferably, the antenna/waveguide is of pyramidal shape. Preferably, the antenna/waveguide exhibits functions of phi and/or pi. However, any geometric form employing these functions can be used for the antenna/waveguide. When it is of pyramidal shape, the primary (apex) coil is preferably connected near or at the apex of the antenna/waveguide. The shape and size of the antenna/waveguide can be optimized depending on the intended use of the generator.

[0030] Typically, the generator further comprises an insulating base on which the antenna/waveguide is placed. The size and shape of the insulating base can also be optimized, depending on the intended use of the generator.

[0031] Typically, the output of the apex coil-antenna/waveguide series resonant circuit or that of the secondary coil is harvested. One way to do this is by connecting to a step-down transformer and rectifier-capacitor-load resistance. The optimal circuit can be selected by one of ordinary skill in the art to optimize power extraction. The load draws power from the generator.

[0032] The driver can supply AC or a combination of AC-DC power to activate the resonant circuit.

[0033] Typically, the antenna/waveguide is positioned in the general North-South direction. In this arrangement, when the antenna/waveguide is of pyramidal shape, the height of the pyramid can vary from about 0.1 m to about 1000 m. The optimal pyramid size is a function of the power requirements. However, a pyramid can be built as high as 1 km in height. The base surface area of the pyramid may range from about 0.01 m^2 to about 1,000,000 m^2. Naturally, other heights and base surface areas or shapes can be used for particular applications. The numbers of sides can also vary. When the pyramid is small (e.g., the 6.26 feet base length described in this application), there is an insufficient atmospheric potential gradient on its apex to trigger the attraction of energy. In such event, a driver is necessary to bring the pyramid to the electric potential necessary for its harvesting function.

[0034] Another embodiment of the present invention is an electric generator for harvesting the energies of atomic oscillators comprising:
